Texas Commission on Environmental Quality

INTEROFFICE MEMORANDUM

To: Commissioners Date: May 4, 2007

Thru: LaDonna Castañuela, Chief Clerk
Glenn Shankle, Executive Director

From: David C. Schanbacher, P.E., Chief Engineer, DCS
Chief Engineer's Office

Subject: Adoption of one TMDL for bacteria in Upper Oyster Creek

Issue Consideration to adopt one final TMDL for bacteria in Upper Oyster Creek (Segment 1245) of the Brazos River Basin, in Fort Bend County, as a certified update to the State of Texas Water Quality Management Plan to satisfy federal water quality management planning requirements.

Background and Current Practice One draft TMDL has been prepared as required by Section 303(d) of the Clean Water Act. TMDLs must be submitted to U.S. EPA for approval as certified updates to the State of Texas Water Quality Management Plan (WQMP). Prior to submission of TMDLs to EPA, TCEQ staff request approval from the commission to release the draft TMDLs for a formal public review and comment period. After the public comment period, TCEQ staff make appropriate changes to the draft TMDLs and document public comments for the record. The next step is to request that the commission adopt and certify the final TMDLs as an update to the State of Texas WQMP. The commission approved TMDLs are then forwarded to U.S. EPA for their final approval or disapproval within 60 days.

Question Does the commission approve the Executive Director's request to adopt the final TMDL for bacteria in Upper Oyster Creek (Segment 1245) as an update to the State of Texas WQMP?

1. (20 points) A particle of mass m moves in a potential $V(x) = \frac{1}{2}kx^2$.

(a) Find the energy levels.

(b) Find the wave function for the ground state.

2. (20 points) A particle of mass m moves in a potential $V(x) = \frac{1}{2}kx^2 + \frac{1}{4}bx^4$.

(a) Find the energy levels to first order in b .

(b) Find the wave function for the ground state to first order in b .

3. (20 points) A particle of mass m moves in a potential $V(x) = \frac{1}{2}kx^2 + \frac{1}{4}bx^4 + \frac{1}{6}cx^6$.

(a) Find the energy levels to first order in b and c .

(b) Find the wave function for the ground state to first order in b and c .

4. (20 points) A particle of mass m moves in a potential $V(x) = \frac{1}{2}kx^2 + \frac{1}{4}bx^4 + \frac{1}{6}cx^6 + \frac{1}{8}dx^8$.

(a) Find the energy levels to first order in b , c , and d .

(b) Find the wave function for the ground state to first order in b , c , and d .

Upper Oyster (Segment 1245) TMDL for Bacteria Summary Outline – April 9, 2007

I. Introduction

- The goal of this project is to determine the allowable bacteria loading that will enable Upper Oyster Creek to meet its contact recreation use.
- The commission approved the release of *One Total Maximum Daily Load for Bacteria in Upper Oyster Creek, Segment 1245*, for public comment at the February 7, 2007, commission agenda. The public comment period was held from February 23 to March 26, 2007. A public meeting to receive oral public comments was held in Sugar Land on March 15, 2007. Oral comments were received from Quail Valley Utility District and the Houston District of the Texas Department of Transportation. Written comments were received from the City of Missouri City, the Harris County Public Infrastructure Department, Fort Bend County Municipal Utility District, the City of Sugar Land, and the Texas Department of Transportation's Environmental Affairs Division. Preliminary written comments were received from EPA.

II. Background Information

- Upper Oyster Creek (Figure 1) is a freshwater stream located in the Brazos River Basin, southwest of Houston, Texas, in northern Fort Bend County. It is approximately 54 miles long and has a watershed area of 110 square miles.

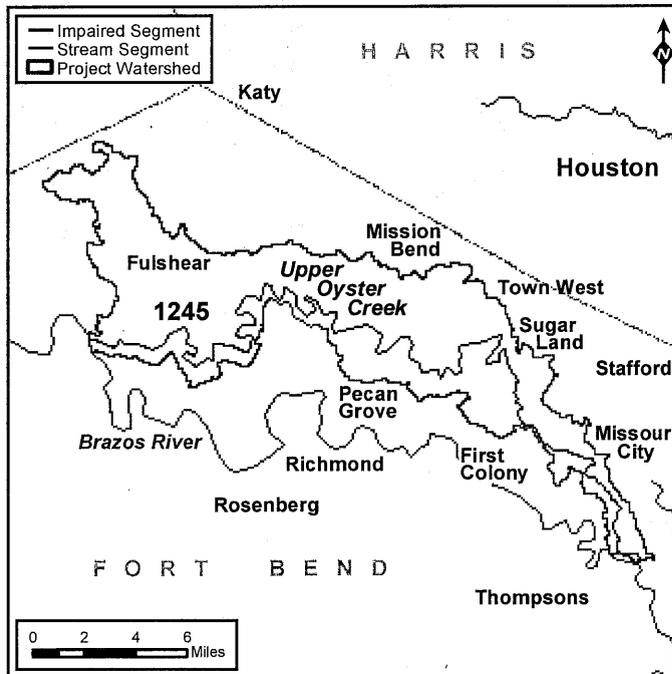

Figure 1. Upper Oyster Creek Watershed

- The segment called "Upper Oyster Creek" actually includes portions of several water bodies, and has been significantly modified from natural conditions. It begins at the Gulf Coast Water Authority (GCWA) Shannon Pump Station on the Brazos River and continues through Jones Creek to its confluence with Oyster Creek, through the City of Sugar Land to its confluence with Flat Bank Creek, through Flat Bank Creek to its confluence with the diversion canal, through the diversion canal to its confluence with Steep Bank Creek, and finally through Steep Bank Creek to its confluence with the Brazos River.
- Three small dams on Upper Oyster Creek are located on the watercourse around the City of Sugar Land. The dams form impoundments to maintain nearly constant water levels for industrial and recreational uses. These off-channel lakes create "lakefront" property with commensurate aesthetic and monetary value.
- There are two distinct hydrologic reaches within the Upper Oyster Creek segment. The upper reach extends from the GCWA Shannon Pump Station on the Brazos River to Dam #3 within the City of Sugar Land. The lower reach begins at Dam #3 and continues downstream to its confluence with the Brazos River. A TMDL allocation has been calculated for each of these two reaches.
- Fort Bend County is rapidly urbanizing. This is particularly evident in the lower portion of the watershed, which includes the cities of Stafford, Missouri City, and Sugar Land.

III. Problem Definition

- Upper Oyster Creek was first placed on the State of Texas 303(d) List for bacteria in 1996, although high levels of indicator bacteria were noted for many years before that.
- A TMDL project was initiated to quantify appropriate reductions of *E. coli* necessary to comply with established water quality standards.

IV. Endpoint Identification

- The primary endpoint for this TMDL will be based on the single sample criterion (394 cfu/100mL). In doing so, the geometric mean criterion (126 cfu/100 mL) should be met as well.

V. Source Analysis

- Bacteria may come from several sources, both point and nonpoint.

- Potential point source dischargers in the Upper Oyster Creek watershed include 15 facilities permitted to discharge wastewater and two facilities permitted for land application of waste material (animal and sewage).
- Probable nonpoint pollution sources in the Upper Oyster Creek watershed include malfunctioning septic tanks, livestock, pets, and wildlife.
- Storm water in the Upper Oyster Creek watershed is another source of bacteria. Bacteria concentrations throughout the system were much higher during rainfall runoff events.

VI. Linkage

- Historical data collected in Upper Oyster Creek dating back to the 1970s indicate that high levels of indicator bacteria are not a new problem for the watershed.
- For the TMDL, additional bacteria (*E. coli*) sampling began in October 2002 and continued through November 2004. Two sampling programs were conducted for two different purposes. From October 2002 through August 2003, 12 approximately monthly surveys were performed on a set schedule to provide the data to assess *E. coli* levels in the Upper Oyster Creek watershed. From March 2004 through November 2004, an additional 12 surveys were performed at selected stations and with the intent of modifying sampling dates to allow the capture of some rainfall-runoff events. The later surveys were conducted as part of a bacterial source tracking study.
- The assessment survey results showed *E. coli* exceeded both the geometric mean and single sample criteria through much of Upper Oyster Creek and its tributaries. Both high and low *E. coli* measurements were observed throughout the year. This observation suggests a lack of seasonality for bacteria in Upper Oyster Creek. However, bacteria levels in Upper Oyster Creek are clearly tied to rainfall-runoff events. The runoff events resulted in much higher *E. coli* counts without exception.
- Bacterial source tracking (BST) sampling was conducted between March and November of 2004. The results of the BST study confirmed that the bacteria in Upper Oyster Creek come from a variety of sources, including humans, pets, livestock, and wildlife (avian and mammalian). No particular source group dominated any of the sampling stations.

VII. Allocations

- Load allocations were calculated using the following equation:

$$\text{TMDL} = \sum \text{WLA} + \sum \text{LA} + \text{MOS}$$

Where

WLA = wasteload allocation (point source contributions);
 LA = load allocation (nonpoint source contributions); and
 MOS = margin of safety.

- Table 1 below summarizes the load allocations for both reaches of Upper Oyster Creek. Note that daily allocations are given in billions of cfu per day for ease of comparison.

Table 1. TMDL Allocation Summary for Upper Oyster Creek Bacteria

Allocation Reach 1	
Existing Loading	4,570 billion cfu/day
Allowable Loading	1,453 billion cfu/day
Waste Load Allocation	1,066 billion cfu/day
Load Allocation	387 billion cfu/day
Margin of Safety	Implicit
Allocation Reach 2	
Existing Loading	7,492 billion cfu/day
Allowable Loading	1,682 billion cfu/day
Waste Load Allocation	501 billion cfu/day
Load Allocation	1,181 billion cfu/day
Margin of Safety	Implicit

VIII. Margin of Safety

- This TMDL uses an implicit margin of safety. Using only data exceeding the single sample criterion provided an implicit margin of safety, since *E. coli* concentrations meeting the criterion (i.e., the data with values ≤ 394 cfu/100 mL) were measured with relatively high frequency at each of the six stations and not included in the analysis.
- This approach has an additional implicit margin of safety based on the state's water quality assessment methodology. This methodology specifies that 25 percent or less of the data can exceed the single sample criterion and still support the contact recreation use. These potentially allowable exceedances were not factored into the load reduction analysis, which instead rigorously made use of all exceedance values.

IX. TMDL

$$\text{TMDL} = \sum \text{WLA} + \sum \text{LA} + \text{MOS (implicit)}$$

TMDL Allocation Reach 1 = 1,066 billion cfu/day + 387 billion cfu/day

TMDL Allocation Reach 2 = 501 billion cfu/day + 1,181 billion cfu/day

In order to meet the TMDL, reductions of **73 percent** are required for both allocation reaches.

Response to Public Comment
TMDL for Bacteria in Upper Oyster Creek (Segment 1245)
 April 11, 2007

Tracking Number	Date Received	Affiliation of Commenter	Summary of Request or Comment	Summary of TCEQ Action or Explanation
001_01	3/15/07	Quail Valley Utility District (Oral and Written)	The commenter noted that they fully support the endeavor to find and solve the bacterial problem in this stream segment. There is often an assumption that because bacteria levels are high, that human sources (sewage) are the main contributing factor. This TMDL has shown that there are other sources that contribute to the high bacterial counts in Oyster Creek (Segment 1245). The commenter referred to the bacterial source tracking data as "Very enlightening." Although the TMDL was extended 2 years for further study and ribotyping bacteria, the Stakeholder process was circumvented in August 2006 and the Stakeholder Group had no input to the final Technical Support Document that this TMDL came from. The final document was produced without Stakeholder consideration.	The support of the TMDL is appreciated. No changes have been made to the TMDL based on this comment.
001_02				The Upper Oyster Creek TMDL project was extended one year beyond what had originally been planned, although that was to allow an extra year of sampling for the dissolved oxygen portion of the project, being covered under a different TMDL document. The load allocations and other relevant points of the bacteria TMDL document were discussed at a stakeholder meeting on December 14, 2006, three months before the comment period began. Stakeholder input has always been welcomed, both at meetings and at any other time. On February 7, 2007, stakeholders were sent notice of the comment period for the TMDL document well before it started. Finally, the TMDL document presented for public comments such as these is not the final document, but a draft which may be changed as needed based on comments. No changes have been made to the TMDL based on this comment.
001_03			PROBLEM DEFINITION: The Bacteria ribotyping indicates that only 14.2% of the bacteria in the segment come from human Sources. Even the sample station with the highest human contribution is 21.4%, leaving 78.6% to other contributors like birds, wildlife, livestock, pets and unknown sources. Most of the wet weather influences appear to DECREASE the Human % contribution. The commenter noted that the draft TMDL document listed 93%	Bacteria source tracking (BST) results indicate that the sources of bacteria in Upper Oyster Creek include humans, livestock, pets, and wildlife. There were no statistically significant differences in sources observed between runoff and non-runoff conditions. No changes have been made to the TMDL based on this comment.
001_04				Any improper discharges of household sewage need to be

			<p>of housing units in 1990 were connected to municipal sewer systems, 6% to septic tanks and 1,400 houses were not connected to anything but a ditch. Whose jurisdiction are these unconnected and septic tank discharges in? Aren't there requirements at the State and County Level that monitor and enforce this type of activity?</p>	<p>investigated and correctional actions enforced by TCEQ Region 12 staff in incorporated areas and Fort Bend County authorized agents in unincorporated areas within the Upper Oyster Creek watershed. The comment about 1,400 houses not being connected to anything but a ditch seems to be a result of confusing wording in the draft TMDL, which stated that in 1990 "approximately 1,400 housing units in the watershed were reportedly not connected to a sanitary sewer system." That number actually included the number of households using septic tanks. The wording has been clarified in the final TMDL document.</p>
001_05			<p>END POINT IDENTIFICATION: The TMDL assumes that the Permitted Wastewater Treatment Plant (WWTP) Dischargers are discharging at the maximum level of 394 cfu/100ml, at the current and permitted flows. This is not the case. Most Dischargers operate at levels WAY BELOW that. The Missouri City Steepbank Plant for example monitors Fecal Coliform daily. This is required because the Plant utilizes Ultra Violet (UV) Light for disinfection, instead of chlorination and dechlorination. Missouri City's fecal coliform geometric mean (average) has been less than 10 cfu/100 ml for the last 5 years. Calculating a reduction from 467 to 126 cfu/100 ml in Reach 1 is not going to change the % contribution from Human Sources if the % of Human Sources is not coming from a Wastewater Plant Discharge. The commenter points out that effluent monitoring was not conducted, so we don't know how much of the human component was from WWTP Discharges.</p>	<p>The TMDL document does not assume that the permitted wastewater treatment facilities are discharging at the level used in the allocation process (the single sample criterion of 394 cfu/100 ml). This is addressed in the document with the statement, "However, based on the requirements in permits for disinfection and the limited bacteria data available for effluents from permitted facilities in the Upper Oyster Creek watershed, these treatment facilities are routinely expected to discharge well below the allowable single sample criterion." Using the single sample criterion in the allocation process is a practical means to prevent overly (and needlessly) restrictive limits on the permitted facilities, while also ensuring treatment and disinfection that will control bacteria within the established water quality standards. Also, federal rules require TMDL allocations for wastewater treatment facilities (WWTFs) be calculated at full permitted flow. No changes have been made to the TMDL based on this comment.</p>
001_06			<p>The TMDL for Bacteria refers to Upper Oyster Creek failing to meet the Aquatic Life use criteria due to depressed levels of dissolved oxygen. The commenter says that if Oyster Creek Segment 1245 did not have flow from the Gulf Coast Water Authority, from the WWTP dischargers, and from rainfall events, this segment would be an intermittent stream and might not meet the aquatic life use on its own.</p>	<p>This TMDL is only addressing the contact recreation impairment. The aquatic life use (dissolved oxygen) impairment will be addressed in a separate TMDL project in its development stage. No changes have been made to the TMDL based on this comment.</p>
001_07			<p>SOURCE ANALYSES: One minor correction on Table 2: Missouri City utilizes UV disinfection and not Chlorination/Dechlorination.</p>	<p>The change has been made as suggested.</p>
001_08			<p>The commenter recognizes the potential for sanitary sewer overflows and WWTP excursions, but thinks the compliance</p>	<p>The TCEQ affirms that sanitary sewer overflows are not allowable discharges and not an allowable loading to the</p>

	<p>history for the permittees during the TMDL study would indicate a very high percentage of compliance - not 100%, but very close. The SSOs and WWTP excursions are generally minimal and are resolved very quickly due to media attention, public scrutiny, TCEQ enforcement, etc... if violations persist.</p> <p>POLLUTANT LOAD ALLOCATION: Continuous waste load allocation at the maximum bacteria criterion, distorts the ability to achieve the goal. If the WWTP dischargers are not the contributing factor to the human contribution, there will be no change in the bacteria levels in Oyster Creek Segment 1245.</p>		<p>impaired water. No changes have been made to the TMDL based on this comment.</p>
001_09			<p>The TMDL document does not assume that the permitted wastewater treatment facilities are discharging at the level used in the allocation process (the single sample criterion of 394 cfu/100 mL). Using the single sample criterion in the allocation process is a practical means to prevent overly (and needlessly) restrictive limits on the permitted facilities, while also ensuring treatment and disinfection that will control bacteria within the established water quality standards. The waste load allocation also includes storm water in permitted areas. No changes have been made to the TMDL based on this comment.</p>
001_10	<p>The recommendation that the Wastewater Treatment Plant Dischargers monitor for fecal coliform or e-coli bacteria, does not recommend a frequency. If the frequency is daily for the 14 dischargers that are not currently required to monitor bacteria, the annual cost for the 14 could range between \$150,000 and \$200,000 per year. Quail Valley UD would prefer to spend their portion of that money finding and solving the bacteria problem than spending it on lab analyses that will not have any effect on the bacteria levels</p>		<p>Past evidence indicates that wastewater treatment facilities discharging into Upper Oyster Creek are properly run and maintained, and that the effluent contains very little bacteria almost all of the time. However, the potential for problems exists, and some kind of monitoring plan for effluent from the facilities would provide assurance that increased bacteria concentrations in effluent are not occurring, and allow for the quick detection and correction of any problems that arise. Options could include TCEQ inspections and monitoring of WWTF effluent, routine monitoring by WWTFs (at a frequency and duration to be determined during the implementation phase of the project, if deemed necessary), routine examination of self-reporting data for chlorine residuals, or others. The wording has been clarified in the final TMDL document to allow flexibility during implementation.</p>
002_01	<p>Refinement of Water Quality Standard Should Precede TMDL Development: The current water quality standard for contact recreation has been inappropriately applied to all fresh waters and was adopted by the TCEQ based on federal studies and guidance. The current standard has not been studied or refined by Texas researchers and has been adopted based on federal studies conducted in Oklahoma and Pennsylvania with different climate and aquatic conditions than those found in Texas. In addition, the current standard does not distinguish between swimming, boating,</p>	<p>Texas Dept. of Transportation – Houston District (Via PBS&J) (Oral)</p>	<p>This TMDL is based on current water quality standards approved for the state of Texas. In the event that new standards are determined to be more appropriate for Upper Oyster Creek, the TMDL would be revised for those standards. To date, no requests for revisions to the current water quality standards for segment 1245 have been received during the publicly held triennial standards revisions or public meetings held when wastewater permits were drafted for this segment. Texas water quality standards</p>

		<p>wading, hiking, and other recreational uses near, on, or in water. The current standard also does not recognize physical constraints or other dangers that would preclude certain recreational uses, such as shallow depths, high velocity flows, or pumped flows.</p> <p>The commenter said that this situation has led to inappropriate impairment listings and inappropriate TMDL development efforts throughout the state, and for the Upper Oyster Creek watershed. A requirement to achieve a full body contact swimming use... is not an appropriate or beneficial outcome. Legal requirements will then compel the TCEQ's permit writers to alter discharge permit conditions to achieve these load reductions. It is likely that all of the small municipal separate storm sewer system (MS4) operators will be unable to obtain permit coverage under the general permit for small MS4's and will be required to obtain an individual permit. TxDOT and other local stakeholders could then be compelled to design, install, and operate substantial treatment systems to achieve excessive bacteria load reductions in storm water runoff.</p> <p>The Houston District believes that the public and private expenditures necessary to comply with pollutant discharge permit requirements revised due to TMDL implementation will cause widespread economic harm and are an inefficient use of public and private funds, particularly because the expenditures are seeking to achieve an inappropriate water quality standard.</p> <p>TMDL Document Should Formally Reference Pending Implementation Plan: The commenter stated that TCEQ TMDL staff have promised stakeholders that while the TMDL will be adopted with extremely low waste load allocations for storm water and wastewater discharges, point source permits will not be reopened and modified to conform to the adopted waste load allocation until after an Implementation Plan has been developed and approved. That approach also does not conform to state and federal law. Stakeholders are justifiably fearful of this type of promise, because under state and federal law, point source permits must be consistent with TMDL waste load allocations once a TMDL is formally adopted. The Houston District believes that revisions to water quality standards should precede TMDL development however, if that is not possible, the TMDL should contain legally enforceable provisions which defer point source</p>	<p>are in a period of review, and are currently going through public workgroups. A formal public hearing for comment on the standards is anticipated in the spring of 2008. No changes have been made to the TMDL based on this comment.</p> <p>The Implementation Plan is explicitly referenced in the TMDL document. According to federal law, TMDLs must be written to meet the water quality standards and cannot be phased to address only a portion of the load. However, a new section was added to the TMDL document about "Implementation Processes to Address the TMDL." This additional language discusses how the Implementation Plan will work to achieve the pollutant loading goals of the TMDL, including the potential for a phased implementation approach.</p>
002_02			

	<p>permit modifications until adoption of the TMDL implementation plan, developed in concert with all watershed stakeholders.</p> <p>As a Last Resort, Adopt a Phased TMDL: If refinement of the applicable water quality standard is not possible prior to TMDL development, and if linking the TMDL to the pending implementation plan is not possible, then TxDOT strongly urges the TCEQ to adopt a "Phased TMDL" as defined in the August 2, 2006 EPA memorandum from Benita Best-Wong to all EPA regions. A "Phased TMDL" is defined in the memorandum as follows:</p> <p><i>The use of the term "phased TMDLs" should be limited to TMDLs that for scheduling reasons need to be established despite significant data uncertainty and where the state expects that the loading capacity and allocation scheme will be revised... Phased TMDLs may... occur when a revision of the applicable standard is underway and will necessitate development of a second phase, revised TMDL to comply with the new standard.</i></p>		
002_03	<p>1. Executive Summary</p> <p>a. Add Discussion of Applicable Water Quality Standard: TCEQ should add a clear discussion of the applicable water quality standard (both use and criterion) to the summary. It is important that the readers and decision makers understand that the designated use is <i>contact recreation</i>, which involves full head immersion swimming.</p> <p>b. Add Discussion of Basis of Water Quality Criterion: The commenter states again that the water quality standards used were derived from studies in areas that don't match Houston's climate, the riparian nature of Oyster Creek, and the actual recreational uses of Upper Oyster Creek. A discussion of the technical basis of the criterion should be added to more completely inform decision-makers and stakeholders, who must fund implementation actions.</p>		
002_04	<p>2. Source Analysis</p> <p>a. Make Distinctions Among Storm Water Point Source Loads: The document does not note the various types of storm water point source discharges that could contribute bacteria loads... including certain industrial facilities, construction sites, and small, medium, and large municipal separate storm sewer systems, which are regulated point sources and should be included in this discussion. TxDOT believes that developing waste load</p>		

002_05		<p>allocations (WLA's) by storm water discharge categories will lead to more cost-effective implementation actions. This approach is also consistent with EPA's policy on the subject.</p> <p>3. Pollutant Load Allocation- Load Duration Curves</p> <p>a. Regrowth Not Considered: The load-duration curve method does not include any regrowth factors, yet literature, and studies conducted by Harris County suggest that in subtropical climates regrowth might explain a large fraction of the observed concentration of bacterial indicators. Regrowth, die-off, and the lack of settling are all complex processes that are not well quantified in the system. There is some evidence to suggest that bacteria regrowth is particularly important in wastewater discharges, even those that are disinfected.</p>	<p>to additional data that TXDOT can provide to assist in this effort. The wording has been clarified in the final TMDL document.</p> <p>The upper allocation reach of Upper Oyster Creek receives very little effluent from wastewater treatment facilities. Therefore, the impact of regrowth in that section is expected to be minimal if present. The lower allocation reach of Upper Oyster Creek is effluent dominated. However, the low number of bacteria exceedances at low flows could indicate that regrowth is not a significant factor here either. Also, this portion of Upper Oyster Creek (in Fort Bend County) is quite different from the bayous in Harris County where the commenter references evidence of regrowth as a significant issue. The water in this part of Upper Oyster Creek is not as turbid nor as deep as those bayous, allowing much greater sunlight penetration, an important factor in bacteria die-off. In any case, the issue of regrowth may need to be explored more fully as it relates specifically to Upper Oyster Creek during the implementation phase of the project. No changes have been made to the TMDL based on this comment.</p>
002_06		<p>4. Pollutant Load Allocation- Waste Load Allocation (Continuous)</p> <p>a. Some Dry Weather Loads Are More Appropriately Handled in the Load Allocation: Storm water permitting regulations define certain "allowable non-storm water discharges," such as lawn watering, foot drains with uncontaminated groundwater, and similar discharges. Recent studies by Harris County have illustrated that many of these allowable non-storm water discharges actually contain elevated concentrations of indicator bacteria. Elevated levels appear because natural bacteria are added to sheet flows and storm water flows across and through lawns and other areas with natural soils. Because MS4 operators cannot regulate or control bacteria loads in these "allowable non-storm water discharges" these bacteria loads should be considered part of the formal TMDL Load Allocation (LA) along with the other uncontrollable nonpoint sources. The District urges the TCEQ to explicitly quantify a bacteria load allocation to allowable stormwater discharges. Some fraction of the defined continuous WLA should be removed and placed in the LA.</p>	<p>The commission is aware that a permittee is afforded the opportunity to identify allowable discharges. However, it is not clear to which specific TPDES permit authorizing discharges to the Upper Oyster Creek watershed the commenter is referring. While there are environmentally adapted bacteria in soils that mimic fecal coliform under standard testing and culturing, such has not been shown to be the case for <i>E. coli</i>. Therefore, if <i>E. coli</i> are in the runoff from lawn watering it is unlikely that the cause is natural bacteria that mimic <i>E. coli</i>, but rather they are a result of a fecal sources from dogs, birds, etc. In the event that the commenter is referring to bacteria from such sources as dogs, birds, etc. as "natural," even if they are carried into the MS4 by an "allowable non-storm water discharge," they are still being discharged to Upper Oyster Creek via a permitted facility, and are therefore best considered a point source. Additionally, elements of what an MS4 identifies in its SWMP include numerous strategies for reducing the pollutant loads discharged from the systems. No changes have been made to the TMDL based on this comment.</p>

002_07			<p>5. Pollutant Load Allocation- Waste Load Allocation (Non-Continuous) a. Make Distinctions Among Storm water Point Source Loads: The commenter states again that the document does not note the various types of storm water point source discharges that could contribute bacteria loads. TxDOT believes that developing waste load allocations (WLA's) by storm water discharge categories will lead to more cost effective implementation actions. This approach is also consistent with EPA's policy on the subject. TxDOT suggests assigning WLA's to the following categories of storm water dischargers: (1) transportation MS4s, (2) county, MUD, and drainage district MS4s, and (3) city MS4s. This could be accomplished by analysis of contributing drainage areas and land surface imperviousness.</p>	<p>See the response to Comment 002_04. The wording has been clarified in the final TMDL document.</p>
002_08			<p>6. Pollutant Load Allocation- Load Allocation a. Dry Weather Sediment-Bound Loads Under-Estimated: Consideration of the resuspension of sediment-bound bacteria during all flow regimes should be added. Bacteria in sediment will leave and enter the water column in a very dynamic manner and the significant sediment loads under these conditions should be considered. TxDOT believes that resuspension should be considered a part of the load allocation.</p>	<p>The TCEQ is aware of studies that have indicated regrowth of <i>E. coli</i> in stream sediments. However, some researchers in the field question the validity and/or applicability of these studies and how they were designed. Resuspended <i>E. coli</i> loads, therefore, may originate from sources directly attributable to the WLA and LA source categories, even though the timing of delivery of these loadings at any Upper Oyster Creek location may be delayed as a result of the processes of settling and subsequent resuspension. The TCEQ acknowledges the complexities inherent in strict quantification of sources and their allocated loadings. To address these complexities, an implicit margin of safety is included in the allocation process and the aforementioned phased or adaptive nature of the Implementation Plan is embraced by the TCEQ. No changes have been made to the TMDL based on this comment.</p>
003_01	3/26/07	City of Missouri City - Public Works (Written)	<p>The commenter questions the appropriateness the water quality standard for total immersion forms of recreation in Segment 1245, particularly in the lower reach which is characterized by generally low water levels in which total immersion would be impossible. The lower reach has also been dredged and widened from its natural state in order to improve storm water drainage from the surrounding suburban area. We support TxDOT's effort to refine the recreational use designations by dividing different types of recreational uses into degrees of immersion.</p>	<p>See the response to Comment 002_01. No changes have been made to the TMDL based on this comment.</p>
003_02			<p>The commenter points out that the draft TMDL notes that, according to the 1990 U.S. Census, 93% of homes in the</p>	<p>See the response to Comment 001_04. The TMDL document has clarified the status of the 1,400 housing units</p>

		<p>watershed were connected to a sanitary sewer system, 6% used septic tanks. The report states that a total of approximately 1,400 housing units in the watershed were not connected to a sanitary sewer system. You have clarified by phone that these 1,400 housing units include both homes connected to septic tanks and homes with no septic tank or sanitary sewer connection. The highest concentrations of septic tanks were in the Four Corners and Fifth Street areas.</p>	<p>and sewage management practices at those residences.</p>
003_03		<p>The TCEQ draft Bacteria TMDL proposes to focus the solution on the 14.2% Human/Sewage component. Within that 14.2%, the only specific recommendation focuses on the 15 domestic wastewater treatment plants operating under permits issued by TCEQ. The draft TMDL recommends that "bacteria monitoring of wastewater effluent be added to all existing and future point sources to supplement disinfection requirements." The draft TMDL is "based on the full allowable discharge for each facility, not the recent discharges, to account for increased loadings that may occur if or when facilities discharge at their maximum allowable levels." This maximum allowed level under their discharge permits is 394 cfu/100 mL. (cfu =colony forming units; mL = milliliters). Of course we would prefer to keep this upper level allowance in our wastewater discharge permit to keep within permit limits when an infrequent higher bacteria discharge event occurs.</p>	<p>It is not the intent of this TMDL to focus bacteria control measures solely on the human/sewage component. All contributors to the bacteria impairment will be considered during the development of the implementation plan, including human sources, livestock, pets, etc. The "continuous" portion of the waste load allocation (not the entire TMDL) is based on the full allowable discharge of the WWTFs. The TMDL also includes allocations to the "non-continuous" waste load allocation (largely storm water in the urbanized area) and load allocation (from all nonpoint sources). No changes have been made to the TMDL based on this comment.</p>
003_04		<p>The commenter states that the study notes of the 15 permitted wastewater treatment plants, only Missouri City's Steep Bank Flat Bank Regional Plant is required to do daily E. coli monitoring under its existing permit. Daily monitoring is required for this plant because it uses UV radiation rather than chlorine for effluent disinfection. The 7-day geometric mean (average) found in testing at the Steep Bank Plant has been less than 10 cfu/100 mL, or well below the maximum 394 cfu, for the last 5 years. Thus, this plant is not a significant source of E. coli bacteria.</p> <p>Unfortunately, effluent sampling at the 15 plants was not included in the TMDL Study, so the portion of the Human/Sewage 14.2% which came from the 15 wastewater treatment plants is not known. But given the known contribution by the City's Steep Bank Plant, we believe that the other permitted plants are responsible for a similar low contribution.</p>	<p>See the response to Comment 001_10. The wording has been clarified in the final TMDL document.</p>

	<p>The commenter then states that the draft TMDL recommendation to add bacteria monitoring of wastewater effluent does not include a recommended frequency of testing, but if done daily at all plants would add approximately \$10,000 to \$14,000 per year to the operating cost of each plant, or a total of approximately \$150,000 to \$200,000 per year.</p> <p>The commenter states that TIAER's study and the local Stakeholder Group input process were cut short prematurely to complete processing of the proposed TMDL on an earlier schedule. We recommend that the proposed daily bacteria monitoring of permitted wastewater treatment plants not be adopted and that the study and Stakeholder Group process be allowed to continue to a thorough completion and meaningful conclusion.</p>			<p>See the responses to Comments 001_02 and 001_10. The wording regarding proposed monitoring has been clarified in the final TMDL document.</p>
003_05	<p>Harris County and HCFCD believe that water quality standards should be refined prior to the adoption of any bacteria TMDL in our region: The commenter questions the applicability of the current water quality standard for contact recreation as it is being applied to Upper Oyster Creek (the language was much the same as the comment by the Texas Dept. of Transportation – Houston District on p. 3).</p> <p>They also state standard does not take into account the likely differences in human health risk between exposure to <i>E. coli</i> from human versus non-human sources; there is a lack of evidence that <i>E. coli</i> from non-human sources is a human health risk. This unfortunate situation has inevitably led to inappropriate impairment listings and inappropriate TMDL development efforts throughout the state.</p>	Harris Co. Public Infrastructure Dept. (Written)	3/26/07	<p>See the response to Comment 002_01.</p> <p>Regarding the human health risk comment, <i>E. coli</i> are generally not a human health risk whether from human or non-human sources. They are indicator bacteria that are generally nonpathogenic.</p> <p>No changes have been made to the TMDL based on these comments.</p>
004_02	<p>As a Last Resort, Adopt a Phased TMDL: If refinement of the applicable water quality standard is not possible prior to TMDL development, then Harris County and HCFCD strongly urge the TCEQ to adopt a "Phased TMDL." The commenter continued with the same language used by the Texas Dept. of Transportation – Houston District on p. 5</p>			<p>See the response to Comment 002_02. The wording has been clarified in the final TMDL document.</p>
004_03	<p>Make Distinctions Among Storm water Point Source Loads: The document does not note the various types of storm water point source discharges that could contribute bacteria loads. It would be helpful if the storm water discharges were further differentiated into their sources, as Harris County research has determined that even discharges allowable under the Clean Water Act, and thus</p>			<p>See the responses to Comments 002_04 and 002_06. Additionally, elements of what an MS4 identifies in its SWMP include numerous strategies for reducing the pollutant loads discharged from the systems. The wording has been clarified in the final TMDL document.</p>

			<p>most NPDES MS4 permits, may contain levels of bacteria that exceed the stream standard. Examples of these types of discharges include air conditioner condensate, freshwater leaks (that have traveled through local soils), and irrigation flows. Consideration and allowance of these types of discharges should be addressed.</p> <p>Discussion of Bacteria as a Living Community: Harris County studies have shown bacterial regrowth to be a large concern within the streams and bayous of Harris County. Harris County strongly recommends that the impact of the bacterial life cycle, including regrowth, be taken into account in local bacteria TMDL studies. Harris County and HCFCD further support the discussion of co-pollutants that likely impact bacteria regrowth rates in the TMDL analysis, such as nutrients. We believe that the state cannot reasonably address bacteria without addressing nutrients, which is the source of food for bacteria. Nutrient levels in White Oak Bayou are generally over 100-times what is expected in unimpaired streams. Probably a similar situation exists for Oyster Creek.</p>	
004_05			<p>Adoption of a TMDL with Realistic Implementation Goals: The commenter estimates that this TMDL proposed will require an 85% and 95% reduction of bacteria from storm sewers from Reach 1 and Reach 2, respectively. Non-structural BMPs such as public education and others found in the Phase II MS4 Permit will not come close to reducing bacteria this much (these reduction levels are higher than a typical wastewater treatment plant). <i>In adopting a TMDL with this reduction rate allocation to storm water, the TCEQ is setting up the regulated community for failure - especially the MS4 operators.</i> The sad part is that cleaning up storm sewer discharges will not likely fix the problem and Oyster Creek will likely still not be able to meet the stream standard.</p>	<p>The sampling conducted for this project showed that the bacteria problem was most severe following rainfall events. However, all contributors to the bacteria impairment will be considered during the development of the implementation plan, including human sources, livestock, pets, etc. It is expected that we will work with MS4 operators (among others) within the watershed to devise workable, useful means of decreasing the load of bacteria to Upper Oyster Creek so that applicable water quality standards will eventually be met. No changes have been made to the TMDL based on this comment.</p>
005_01	3/26/07	Fort Bend Co. Municipal District #25 (Via CDM) (Written)	<p>Endpoint Identification The commenter states that use attainability analysis is necessary to identify the appropriate endpoint for the TMDL and implementation plan development. The commenter states that current contact recreation standards are not applicable to Texas and do not take into account background conditions that would be expected in Upper Oyster Creek.</p>	<p>See the response to Comment 002_01. No changes have been made to the TMDL based on this comment.</p>
005_02			<p>Source of Bacteria in Upper Oyster Creek Watershed The DISTRICT believes that the TMDL has not satisfactorily evaluated all sources of bacteria in the Upper Oyster Creek watershed. Sources that required additional investigation include</p>	<p>See the response to Comment 002_05. No changes have been made to the TMDL based on this comment.</p>

	<p>regrowth, and resuspension of bacteria from sediment. Bacteria load estimates should be developed for each source to indicate the magnitude of their contributions. These loads estimates should then be compared with the bacteria source tracking results to confirm that all sources have been incorporated into the TMDL and their distribution is appropriate.</p>		
<p>005_03</p>	<p>Linkage analysis The US EPA requires a relationship between the source and indicator bacteria. Plots of bacteria concentrations provided in the TMDL do not meet this requirement. The load duration curve should be discussed in this section as that is the basis for linking bacteria sources and water quality targets.</p>		<p>In response to this comment, a discussion of the load duration curve approach has been added to the "Linkage Analysis" section of the TMDL.</p>
<p>005_04</p>	<p>Pollutant Load Allocation The percent reductions for the TMDL are overestimated because bacteria concentrations that meet the standard were excluded from the analysis. Excluding those data biases the regression line high, excludes many of the lower flow samples and overpredicts the loading in the creek. Figures 13, 14, and 15 in the TMDL document are examples where the regression line would be much lower if all points were included in the regression. Requiring reductions that are excessive will have serious, negative financial repercussions and load reductions should be adjusted to address this flaw.</p>		<p>Historical data and data collected specifically for this project demonstrate that Upper Oyster Creek is not meeting its water quality standards for contact recreation due to excessive levels of indicator bacteria (<i>E. coli</i>). For the single sample criterion used as the primary endpoint for this TMDL (394 CFU/100 mL), up to 25 percent of the samples are allowed to exceed the criterion. For the six stations used in determining the load allocations, anywhere from one-third to two-thirds of the samples exceeded the criterion during the sampling conducted for the project. Thus, while all stations were failing to meet the standards, many individual data points are below the criterion. Including all points in the regression line could mathematically result in the line falling below the standard, erroneously implying that no reduction is necessary when the data showed that standards were not being met. Using only the points exceeding the standard in the regression analysis is an acceptable, conservative means of determining a reduction percentage to meet the single sample criterion, and is one of the main ways of providing an implicit margin of safety. Since the state's water quality standards also require the geometric mean criterion for contact recreation to be met (126 cfu/100 mL), all of the data points collected for the project were also used to calculate the geometric means for each allocation reach. The required 73 percent reduction would allow Upper Oyster Creek to meet this criterion as well. No changes have been made to the TMDL based on this comment.</p>
<p>005_05</p>	<p>In addition, load reductions should not be applied evenly across all sources. A breakdown of all sources in the watershed should be</p>		<p>The load duration curve approach provides a means to estimate the amount of bacteria reduction required and</p>

		<p>provided and load reductions for each source identified. Known sources that can be addressed by existing regulatory means should be allocated larger load reductions than other sources.</p>	<p>provides a broad indication of the origin of the bacteria, i.e., point sources and nonpoint sources. Further refinement to identify more precise source categories and bacteria reduction strategies will be conducted during the implementation phase of this project, considering factors such as this type of input. No changes have been made to the TMDL based on this comment.</p>
005_06		<p>Finally, the DISTRICT supports the development of a phased TMDL. Sources that affect water quality when contact recreation would likely occur, such as septic systems, should be prioritized and addressed in the early phases. Other sources, such as wastewater treatment plants which have been shown to have minimal impact on water quality or and stormwater sources which are wet weather sources, should be addressed only when all other sources have been addressed.</p>	<p>See the response to Comment 002_02. The wording has been clarified in the final TMDL document.</p>
005_07		<p>Wastewater treatment plants improve water quality Wastewater treatment plants are not a major source of bacteria to Upper Oyster Creek. Well operated plants have been shown in other Houston TMDL studies (i.e. Buffalo and Whiteoak Bayou watersheds) to operate properly when chlorine residuals are maintained. In fact, research performed in that TMDL has shown the potential for WWTPs to improve water quality by providing clean, disinfected water that dilutes the polluted surface water. Upper Oyster Creek would be an intermittent stream if not for wastewater and additional flow from the Brazos River. The DISTRICT believes that human sources identified in bacteria source tracking should be identified and are related to the malfunctioning septic systems found in non-sewered areas.</p>	<p>The TCEQ agrees that wastewater treatment facilities that are operating properly are not likely to be a significant source of bacteria, and the TMDL document acknowledges that. WWTF sampling conducted as part of the Buffalo and Whiteoak Bayou TMDL project indicated a non-compliance rate of approximately 2%-7% under varying conditions. The flow in Allocation Reach 1 is dominated by treated effluent from wastewater treatment facilities. However, the flow in Allocation Reach 2 is dominated by water pumped into the segment from the Brazos River by the Gulf Coast Water Authority. Finally, identifying and correcting malfunctioning septic systems is expected to be a high priority during the implementation phase of this project. No changes have been made to the TMDL based on these comments.</p>
005_08		<p>Wastewater Treatment Plant (WWTP) Flows Another of the concerns for the DISTRICT is the failure of the TMDL to adequately address growth as required by 40 CFR§130.2(h). According to the Fort Bend County website, Fort Bend County is fourth fastest growing county in the nation among counties over 200,000 in population and is anticipated to have the strongest economic growth in the nation between 2000 and 2030. Population projections indicate over one-half million people will be added to the county in the next 25 years. To support this population influx, construction of new infrastructure and expansion of existing infrastructure is required. Although the</p>	<p>The TMDL is based on currently permitted conditions. Additionally, the "Future Growth" section of the TMDL document states: "Therefore, the effluent of any additional permitted facilities should not result in nonsupport of the contact recreation use. At worst, additional discharges should result in a neutral impact on Segment 1245 by increasing streamflow while adding bacteria at concentrations meeting protective criteria. However, because of disinfection requirements in their permits, these facilities are typically expected to discharge at concentrations less than the bacteria criteria." In order to</p>

<p>specifically allocate loading as part of an allowance for future growth in the TMDL equation, some loading would have to be taken away from either the waste load allocation or load allocation components. No changes have been made to the TMDL based on these comments.</p>	<p>TMDL acknowledges Fort Bend's rapid growth, the wasteload allocation (WLA) in its current form does not account for future population increases. The TCEQ should anticipate these increases in the TMDL rather than react to the growth as it happens. There is no question that the county will continue to grow, and the TMDL should account for this growth explicitly.</p>		
<p>See the response to Comment 001_10. The wording has been clarified in the final TMDL document.</p>	<p>Bacteria Monitoring Requirements Bacteria monitoring on a regular basis is not necessary and would be onerous for WWTP operators and staff. Bacterial analyses have strict time limitations and require specialized handling. (i.e., sterile handling techniques and equipment). In addition, the analytical methodology is expensive to implement and requires expertise and training to obtain reliable and accurate results. Obtaining bacteria samples and performing the analysis would therefore place an undue and unnecessary financial burden on WWTP operators and staff. Sampling concluded in support of the Buffalo and Whiteoak Bayou TMDLs demonstrated that exceedances of the single sample standard occur very rarely, at most 7 to 10% of the time. Plants exceeding the surface water standard were found to have very low chlorine residuals. Therefore, monitoring effluent for bacteria is not necessary to demonstrate compliance. The DISTRICT would much prefer to use financial resources to make effective, visible improvements rather than waste money testing for an unnecessary constituent.</p>		
<p>See the response to Comment 002_01. No changes have been made to the TMDL based on this comment.</p>	<p>Water Quality Standard Assumptions The commenter questions the applicability of the current water quality standard for contact recreation as it is being applied to Upper Oyster Creek. They state that Oyster Creek is rarely used for contact recreation as defined by the TCEQ and that recreational uses of Oyster Creek fit much more closely to the definition of non-contact recreation. Oyster Creek like many other bodies of water in Texas are being inappropriately classified for contact recreation and thus being held standards much more stringent than necessary. They recommend that the water quality standards be refined to reflect bodies of water, such as Oyster Creek, that do not truly meet the definition of contact use recreation.</p>	<p>City of Sugar Land (Written)</p>	<p>3/26/07</p>
<p>See the response to Comment 005_08. No changes have been made to the TMDL based on this comment.</p>	<p>Wastewater Treatment Plant Contributions The City's current wastewater treatment plant (WWTP) contributions come from its South WWTP, whose permitted maximum discharge is 10 MGD. While there is room for</p>		

006_03		<p>growth at this plant, as the City is not currently discharging at its maximum, the "ultimate" contributions the study is based on do not take into account future growth. Given the rapid expansion of the City and Fort Bend County, the waste load allocation (WLA) should project its loads based on ultimate development or at the very least, consider the actual impact of future WWTTP flows. The commenter also points out that well-operated plants have a net positive benefit on the concentration of <i>E. coli</i> in the streams by adding greater volumes of water with lower concentrations of contaminant.</p> <p>Additionally, the emphasis on restrictions on WWTTP loading does not recognize sufficiently that the primary source fecal <i>E. coli</i> identified in the study is not human, but rather animal/avian.</p>	<p>It is not the intent of this TMDL to focus bacteria control measures solely on the human/sewage component. All controllable contributors to the bacteria impairment will be considered during the development of the implementation plan, including human sources, livestock, pets, etc. No changes have been made to the TMDL based on this comment.</p>
006_04		<p>The commenter also states that bacteria monitoring requirements for a WWTTP should be removed if it can show that its discharge is already less than the ambient level.</p>	<p>See the response to Comment 001_10. The wording has been clarified in the final TMDL document.</p>
006_05		<p>Reuse Projects</p> <p>As Fort Bend County gears up to meet the dual water supply challenges of significant growth and equally significant regulatory reductions in groundwater withdrawals, effluent reuse projects represent a viable alternative to both groundwater and dwindling surface water supplies. One of the more feasible alternatives is the use of Bed and banks permits to transport effluent from WWTTP discharges to downstream users. The standards and model do not effectively account for the beneficial nature of such projects, in both the reduction of surface water withdrawals and the wiser use of finite resources. Again, as the quality and concentrations characteristic of the effluent are of better quality than the ambient stream, the addition of reuse flows represents a net positive benefit. However, as the model and standards don't adequately account for their growing use, the TMDLs represent a potential disincentive for this type of project, even though the projects represent a "win/win" scenario for both environmental and human interests.</p>	<p>The load duration curve approach provides a means to estimate the amount of bacteria reduction required and provides a broad indication of the origin of the bacteria, i.e., point sources and nonpoint sources. Detailed water use strategies such as this can be considered during the implementation phase of the project, particularly if such alternatives have been approved and more certain. No changes have been made to the TMDL based on this comment.</p>
006_06		<p>It is anticipated that within 2007, the TCEQ will adopt the proposed Phase II MS4 general permit. When issued, General Permit TXR040000 will authorize the City of Sugar Land to</p>	<p>A Phase II MS4 city must submit a notice of intent to be authorized under a general permit or as an alternative could seek an individual permit by the deadline required under the</p>

			<p>discharge storm water to surface waters of the state (i.e. Oyster Creek). The Phase II general permit is an unfunded mandate requiring the City to develop and implement a storm water management program. With the adoption of these TMDL standards, the City may be required to implement additional costly programs in addition to the Phase II general permit requirements. As this impact is being driven by standards and a model we do not feel are accurate, the potential unfunded mandate these TMDLs represent seem far out of balance with the City's actual contributions, if any, to the impairment of Oyster Creek.</p>	<p>TPDES program and federal Clean Water Act. It is expected that we will work with any MS4 owners/operators within the watershed to devise workable, useful strategies that would decrease the load and impact of bacteria discharged from urban storm sewers so that applicable water quality standards will eventually be met. MS4 permits do not have numerical requirements, but rather have best management practices (BMPs). The TCEQ is hopeful that the TMDL and implementation plan can help the city in putting BMPs where they are needed most, effectively being more cost efficient. No changes have been made to the TMDL based on this comment.</p>
006_07			<p>Economic Impact With the potential for monitoring of WWTP effluent that rarely if ever comes near the set standard, the difficulties caused for potential reuse projects, the lack of adequate consideration for future growth and the potential impact on MS4 permits, the TMDLs represent an appreciable negative economic impact on the City.</p>	<p>See the response to Comment 001_10. The wording has been clarified in the final TMDL document.</p> <p>The other portions of this comment were discussed in other responses (006_02 and 006_06) to this commenter.</p>
007_01	3/26/07	Texas Dept. of Transportation – Environmental Affairs Division (Written)	<p>The TCEQ TMDL analysis has determined that a 73% reduction in bacteria loading is required for the segment to meet the designated use of contact recreation. TCEQ makes a point in the "Source Analysis" section of the TMDL to state that municipal separate storm sewer systems (MS4s) are point source discharges subject to regulation under the TPDES permit program. Although bacteria concentrations in storm water runoff are typically elevated, it is important to recognize that TxDOT MS4s are not "point source origins" of bacteria. TxDOT storm water systems were designed prior to TPDES permit requirements, and were constructed to intercept runoff, divert floodwater away from transportation facilities, and to provide traffic safety. As such, these systems capture runoff from a myriad of different areas such as commercial, retail, farm, and suburban neighborhoods. These MS4s simply convey storm water that may additionally transport pollutants from regulated point sources and from area unregulated non-point sources. Dry weather screenings, spill response, and other best management practices are utilized by TxDOT to ensure these MS4 discharges meet TPDES permit requirements. Where TxDOT allows point source discharges to enter the MS4, we verify that the discharge is authorized under TPDES, and rely on the permit requirements to ensure the discharge is protective of</p>	<p>The TCEQ recognizes that many sources that are traditionally thought of as nonpoint in origin contribute pollutants to storm water. However, for regulatory purposes, storm water regulated by a permit (such as the pending Phase II MS4 permit) falls under the definition of a point source, and is allocated as such in this TMDL. It is expected that we will work with any MS4 owners/operators within the watershed to devise workable, useful strategies that would decrease the load and impact of bacteria discharged from urban and highway right of way storm sewers so that applicable water quality standards will eventually be met. No changes have been made to the TMDL based on this comment.</p>

007_02		water quality. TxDOT supports the recommendation on Page 37 that bacteria monitoring of wastewater effluent be added to point source discharges of domestic wastewater to supplement disinfection requirements.	See the response to Comment 001_10. The wording has been clarified in the final TMDL document.
007_03		On Page 30 of the TMDL document, under the Allocation Process discussion, it is stated that the TMDL load allocation for Segment 1245 was performed to "account for the pending general permit for small Separate Storm Sewer Systems." It is important to formally recognize that these are not new and proposed discharges of storm water. Instead, these are ongoing discharges to Segment 1245 that will soon be required to meet TPDES storm water management plan requirements to reduce or eliminate pollutants in storm water runoff.	Additional wording to make this point has been added to the document.
007_04		In the allocation process for the TMDL, TCEQ has effectively parceled dischargers into three groups: municipal wastewater treatment plants (identified as "WLA"); discharges from Phase II MS4s (identified as "WLA non-continuous"); and all non-regulated, nonpoint sources (identified as "LA"). The waste load allocation for the WLA group was subtracted from the allowable TMDL, and the remaining bacteria loading was identified as available to the remaining groups. A simple ratio of percent area for urbanized areas versus non-urbanized areas within the drainage area was used to divide the remaining allocation. This methodology is based on "occupied area" and does not account for any differences in the potential pollutant contribution from these two very different groups. It may even be argued that there is no need to separate the remaining allocation between these two groups. TPDES Phase II MS4 permits may be developed to include any management plan requirements specific to the control of bacteria, and education and voluntary measures may be identified and used to control bacteria from non-regulated sources, as is described in the "Implementation and Reasonable Assurances" section.	As the commenter indicates, this TMDL made use of simple area ratios to divide allowable load remaining after the calculation of the continuous waste load allocation into the non-continuous waste load allocation and the load allocation. The TCEQ recognizes that further refinement of these allocations will need to take place during the implementation phase of the project. It is expected that we will work with any MS4 owners/operators within the watershed to devise workable, useful strategies that would decrease the load and impact of bacteria discharged from urban and highway right of way storm sewers so that applicable water quality standards will eventually be met. No changes have been made to the TMDL based on this comment.
007_05		Storm water runoff is generally recognized as containing significant levels of bacteria. We support efforts, such as Bacteria Source Tracking, to identify the largest sources of bacteria to this watershed, in order that they may either be controlled through regulatory requirements, or through voluntary controls and commitments at their source. TxDOT has proposed an agency-sponsored study, "Bacteria Levels in Roadway Runoff to be	The TCEQ agrees that additional research into specific sources of bacteria through Bacterial Source Tracking or other means could be valuable in identifying specific sources of bacteria in Upper Oyster Creek and other water bodies around the state. The TCEQ encourages the TxDOT to collaborate with us on developing this study so that the results of the study can be utilized in implementation

007_06			<p>conducted in fiscal year 2008. TxDOT believes that research is needed to determine concentrations and discharges of indicator bacteria from roadways, to better understand bacteria contributions, potential sources, and controls.</p> <p>If the proposed TMDL is approved, TxDOT requests to be a participant stakeholder in the development of an implementation plan for the TMDL.</p>	<p>planning. No changes have been made to the TMDL based on this comment.</p>
				<p>Under the established ground rules of the Upper Oyster Creek Steering Committee, new members "must be recommended by an existing committee member and approved by consensus of existing members." As the steering committee does not have the maximum allowable number of participants, it is anticipated that TxDOT can request and receive inclusion in the steering committee by its current members. TxDOT is welcome to attend all steering committee meetings, and the request to be added to the group could be undertaken at any one of them. No changes have been made to the TMDL based on this comment.</p>

TEXAS COMMISSION ON ENVIRONMENTAL QUALITY

A RESOLUTION

adopting one total maximum daily load (TMDL) for bacteria in Upper Oyster Creek (Segment 1245) of the Brazos River Basin, in Fort Bend County, as a certified update to the State of Texas Water Quality Management Plan.

TCEQ Docket No. **2006-1967-TML**

WHEREAS, under 40 Code of Federal Regulations §130.6, the State must ensure that State and areawide Water Quality Management Plans (WQMP) together include all necessary plan elements and that such plans are consistent with one another;

WHEREAS, under Texas Water Code, §26.037, The Texas Commission on Environmental Quality (commission) is charged with the approval of WQMP updates;

WHEREAS, the Texas Water Code, §5.122 allows for delegation of commission authority to the Executive Director under certain terms and conditions;

WHEREAS, by resolution issued on February 18, 1999 (Resolution), the commission authorized the Executive Director to approve WQMP revisions and updates;

WHEREAS, under the terms of the Resolution, the commission may, in its discretion, choose to consider and approve or disapprove proposed revisions to the WQMP;

WHEREAS, the Executive Director has drafted one TMDL for bacteria in Upper Oyster Creek (see Attachment A) and presented it for the commission's consideration;

WHEREAS, the commission finds that the TMDL for bacteria in Upper Oyster Creek complies with all state and federal law and regulations and are consistent with all other parts of the Texas WQMP;

NOW, THEREFORE, it is resolved and ordered by the commission that the TMDL for bacteria in Upper Oyster Creek (Attachment A) is adopted and shall be submitted to the EPA for approval to be included in the Texas WQMP.

One Total Maximum Daily Load for Bacteria in Upper Oyster Creek

Executive Summary

This document presents the total maximum daily load (TMDL) for bacteria in Upper Oyster Creek (Segment 1245). Upper Oyster Creek extends for approximately 54 miles in rapidly urbanizing Fort Bend County, and has a watershed area of 110 square miles. It is located in the Brazos River Basin southwest of Houston.

Sampling conducted as part of this project confirmed that Upper Oyster Creek is not meeting its designated contact recreation use. The problem extends through much of the length of the segment and is highly influenced by rainfall runoff events. Potential sources of bacteria in the watershed include humans, pets, livestock, and wildlife. The goal of this project is to determine the allowable bacteria loading that will enable Upper Oyster Creek to meet its contact recreation use.

Upper Oyster Creek can be divided into two hydrologically distinct sections; load allocations were developed for both using the load duration curve method. Based on the analysis of the load allocation scenarios, a 73 percent reduction in bacteria loading in each section is required to meet the contact recreation use.

The TCEQ and its stakeholders will develop an implementation plan that will outline the management strategies needed to restore water quality to Upper Oyster Creek. The continued involvement of the TMDL steering committee will be essential to the success of implementation.

Introduction

Section 303(d) of the federal Clean Water Act requires all states to identify waters that do not meet, or are not expected to meet, applicable water quality standards. For each listed water body that does not meet a standard, states must develop a TMDL for each pollutant that contributes to the impairment of water. The priority for this TMDL development was medium. The Texas Commission on Environmental Quality (TCEQ) is responsible for ensuring that TMDLs are developed for impaired surface waters in Texas.

In simple terms, a TMDL is like a budget that determines the amount of a particular pollutant that a water body can receive and still meet its applicable water quality standards. In other words, TMDLs are the best possible estimates of the assimilative capacity of the water body for a pollutant under consideration. A TMDL is commonly expressed as a load with units of mass per period of time, but may be expressed in other ways. TMDLs must also estimate how much the pollutant load must be reduced from current levels in order to achieve water quality standards.

The TMDL Program is a major component of Texas' overall process for managing surface water quality. The Program addresses impaired or threatened streams, reservoirs, lakes, bays, and estuaries (water bodies) in, or bordering on, the state of Texas. The primary objective of the TMDL Program is to restore and maintain the beneficial uses (such as drinking water supply, recreation, support of aquatic life, or fishing) of impaired or threatened water bodies.

This TMDL will address an impairment to the contact recreation use due to elevated levels of bacteria in Upper Oyster Creek. The ultimate goal of this TMDL is to decrease bacteria concentrations in Upper Oyster Creek to the extent necessary to meet the contact recreation use.

Section 303(d) of the Clean Water Act and the implementing regulations of the U.S. Environmental Protection Agency (EPA) (40 Code of Federal Regulations, Part 130) describe the statutory and regulatory requirements for acceptable TMDLs. The EPA provides further direction for developing TMDLs in its *Guidance for Water Quality-Based Decisions: The TMDL Process* (USEPA 1991). This TMDL document has been prepared in accordance with those regulations and guidelines. The TCEQ must consider certain elements in developing a TMDL; they are described in the following sections:

- Problem Definition
- Endpoint Identification
- Source Analysis
- Linkage Analysis
- Seasonal Variation
- Margin of Safety
- Pollutant Load Allocation
- Public Participation
- Implementation and Reasonable Assurance

The commission adopted this document on Month, Day, Year. Upon EPA approval, the TMDL will become an update to the state's Water Quality Management Plan.

Problem Definition

Upper Oyster Creek was first placed on the state's 303(d) List for bacteria in 1996. However, high levels of indicator bacteria had been noted for many years before that. For example, a use attainability analysis conducted to assess the aquatic life use on Upper Oyster Creek in the early 1990s noted "...many exceedances of fecal coliform have occurred in the past 10 years, especially at US 90A" (Texas Water Commission, 1991). In more recent years (TCEQ, 2002 and 2004), the 303(d) List specified that the portion of the segment "from Highway 90A to Dam #1, located 1.5 miles upstream of Harmon St." was impaired due to the presence of bacteria.

Watershed Overview

Upper Oyster Creek is located in the Brazos River Basin, southwest of Houston, Texas, in northern Fort Bend County. It is identified as Segment 1245 in the *Texas Surface Water Quality Standards* (TCEQ, 2000). It has been subjected to significant hydrologic modification. The segment called “Upper Oyster Creek” actually includes portions of several water bodies. It begins at the Gulf Coast Water Authority (GCWA) Shannon Pump Station on the Brazos River and continues through Jones Creek to its confluence with Oyster Creek, through the City of Sugar Land to its confluence with Flat Bank Creek, through Flat Bank Creek to its confluence with a diversion canal, through the diversion canal to its confluence with Steep Bank Creek, and finally through Steep Bank Creek to its confluence with the Brazos River (Figure 1). Segment 1245 extends approximately 54 miles, and its watershed contains four incorporated areas: Fulshear, Sugar Land, Stafford, and Missouri City. The Upper Oyster Creek watershed covers approximately 110 square miles, about 12.5 percent of the area of Fort Bend County.

Three small dams on Upper Oyster Creek are located on the watercourse around the City of Sugar Land. The dams form impoundments to maintain nearly constant water levels for industrial and recreational uses. These off-channel lakes create “lakefront” property with commensurate aesthetic and monetary value. There are two distinct hydrologic reaches within the Upper Oyster Creek segment. The upper reach extends from the GCWA Shannon Pump Station on the Brazos River to Dam #3 within the City of Sugar Land. The lower reach begins at Dam #3 and continues downstream through Steep Bank Creek to its confluence with the Brazos River.

The GCWA uses the reach above Dam #3 as a section of its Canal System A, which supplies water for irrigation, industrial, and public drinking supply to areas southeast of the watershed in addition to uses in the vicinity of the City of Sugar Land. Dam #3 retains water for Alkire, Eldridge, and Horseshoe Lakes, and also serves to retain water for the GCWA Second Lift Station where water is pumped into the American Canal for transport to the Texas City area.

The hydrology of the reach below Dam #3 is highly influenced by the presence of the dam and the Second Lift Station. Small amounts of seepage do occur through Dam #3, and there is uncontrolled, excess rainfall runoff over the dam into the lower reach. The Second Lift Station, however, operates under most wet-weather conditions to capture portions of the rainfall runoff, which reduces the amount released below Dam #3. The lower reach contains no retention structures, and is characterized by reduced flow composed of small amounts of seepage from Dam #3, contributions from municipal dischargers, natural contributions from the drainage area below Dam #3, and excess rainfall runoff that is not diverted from the upper reach above Dam #3. The reach below Dam #3 is also hydrologically modified, though not for conveyance of water supplies and impoundment of water, but rather for flood prevention.

Data from GCWA Shannon Pump Station and the Second Lift Station were evaluated for trends and general characteristics for the period 1986 through 2000 (TIAER, 2006). Records from the Second Lift Station were used to characterize monthly hydrologic conditions in the upper reach of Upper Oyster Creek, because some, though not all, rainfall runoff is captured and pumped from that station.

Data for the Second Lift Station indicate that the pumped flow increases through the spring (between 1,000 to 3,000 acre-feet per month [ac-ft/mo] on average) to a maximum in July. Pumped flow decreases through the fall and winter to its lowest average rate of 1,325 ac-ft/mo in February. Average annual pumped flow through the segment is over 50,000 ac-ft per year. Annual flows range from a minimum of 28,889 ac-ft pumped in 1997, to a maximum of 69,670 ac-ft pumped in 1995. Existing flow data from the U.S. Geological Survey (USGS) station 08112500 (Brazos River Authority Canal A near Fulshear; no longer in operation) suggest similar characteristics and patterns of pumped flow for the period from 1931 to 1973. Seasonal high flow was observed in the USGS data for the months of April through September, while lower flow was noted in March and October. Flow is usually lowest in the months of November through February.

The dominant land use category in the watershed is pasture, which accounts for 56.1 percent of the total area. The urban areas (urban mixed and residential) occupy 24 percent of land cover within the watershed. Other land uses include rangeland at 9.5 percent, forest at 7.2 percent, and water at 3.2 percent (see Figure 2).

The climate in the Upper Oyster Creek watershed is classified as subtropical, which is defined as having hot, humid summers and dry winters. Between 1970 and 2000, the average annual rainfall was 49.3 inches, as measured at Sugar Land Regional Airport (NOAA, 2004). During this same period, rainfall events of at least 0.1, 0.5, and 1 inch of rain were observed on average 64, 31, and 16 days per year, respectively. The Upper Oyster Creek watershed is within the upper portion of the Gulf Coast Prairies and Marshes ecoregion, an area characterized as containing nearly level, un-dissected plains with native vegetation types composed of tall grass prairie and post oak savanna. The elevation of the area is approximately 80 feet above mean sea level.

Endpoint Identification

All TMDLs must identify a quantifiable water quality target that indicates the desired water quality condition and provides a measurable goal for the TMDL. The TMDL endpoint also serves to focus the technical work to be accomplished and as a criterion against which to evaluate future conditions.

The *Texas Surface Water Quality Standards* (TCEQ, 2000) are rules developed by the TCEQ that provide a basis on which regulatory programs may be carried out. Categories are defined by the TCEQ to describe the way that water bodies in the state are used. Each use category is associated with a suite of criteria developed to protect the continued use of each water body in the state. According to Appendix A of the Standards, the

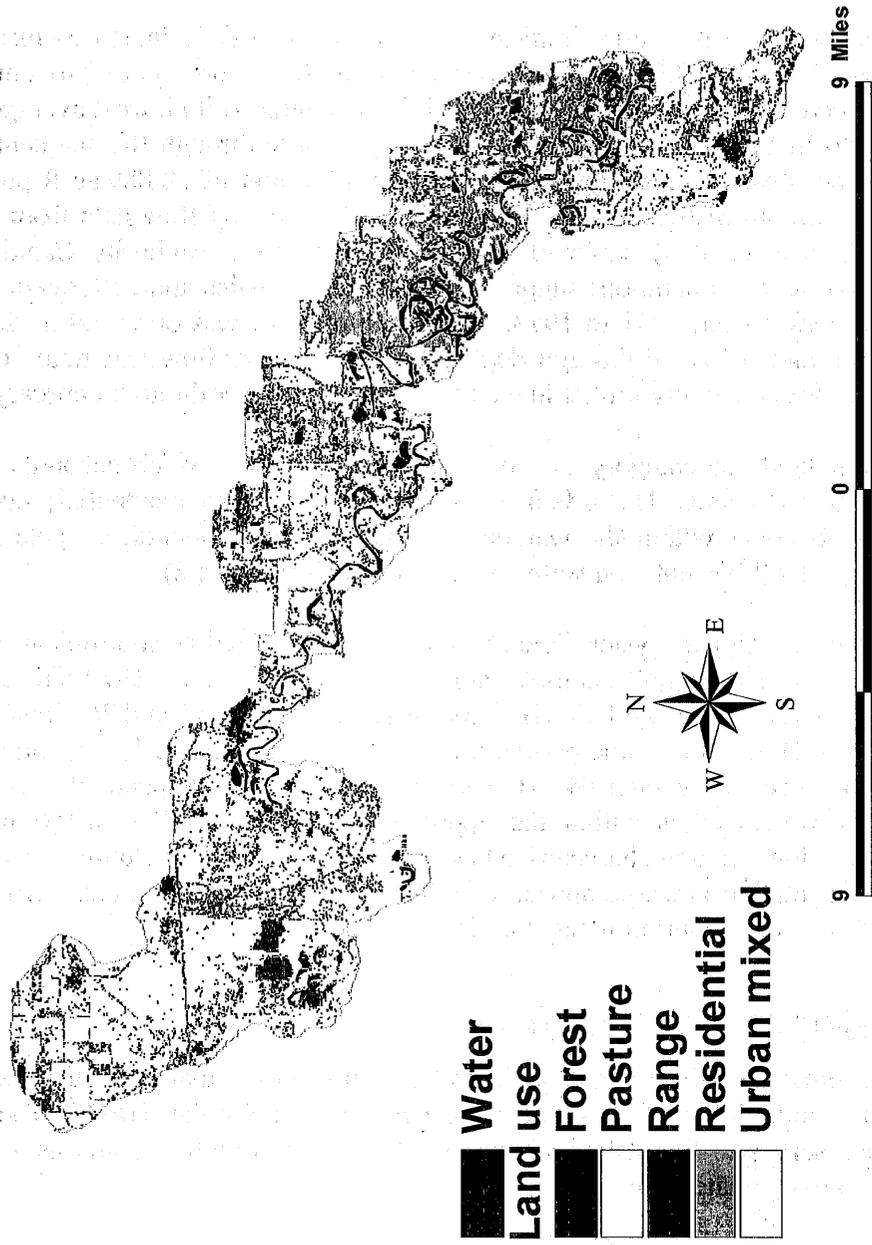

Figure 2. Land use/land cover for the Upper Oyster Creek watershed (Source: Baylor, 1997)

designated uses of Upper Oyster Creek include contact recreation, intermediate aquatic life use, and domestic water supply.

Upper Oyster Creek also fails to meet its aquatic life use due to depressed levels of dissolved oxygen. This TMDL document will only address the bacteria impairment. The dissolved oxygen TMDL will be presented in a separate document at a later date.

The water quality criteria for contact recreation in Upper Oyster Creek are expressed as the number of colony forming units (cfu) of *Escherichia coli* (*E. coli*) per 100 milliliters (mL) of water (Table 1). The contact recreation use is not met if bacteria concentrations exceed either the single sample or geometric mean criteria. However, 25 percent of the samples must exceed the criterion for single samples before the water body is assessed as not supporting the contact recreation use (TCEQ 2003).

Table 1. Numeric criteria for Upper Oyster Creek

Segment	Contact Recreation Use Criteria (<i>E. coli</i>)	
	Single Sample	Geometric Mean
1245 – Upper Oyster Creek	394 cfu/100 mL	126 cfu/100 mL

E. coli replaced fecal coliform as the preferred indicator bacteria for freshwater in Texas in revisions to the Standards in 2000. This change was anticipated while planning the project, and *E. coli* data were collected during all relevant sampling events. *E. coli* is typically not pathogenic. Its presence in water indicates *potential* contamination from the feces of warm-blooded animals. The use of indicator bacteria is necessary because it is not currently feasible to directly measure all potential pathogens in water.

The endpoint for this TMDL is based on the single sample criterion, which will be used for calculating the load allocation. As demonstrated later in the report, if the single sample criterion is met, the geometric mean criterion should be met as well.

Source Analysis

Pollutants may come from several sources, both point and nonpoint. Point source pollutants come from a single definable point, such as a pipe, and are regulated by permit under the Texas Pollutant Discharge Elimination System (TPDES). Storm water discharges from industries, construction, and the separate storm sewer systems of cities are considered point sources of pollution. Nonpoint source pollution originates from multiple locations, usually carried to surface waters by rainfall runoff, and is not regulated by permit under the TPDES. The possible sources of bacteria in Upper Oyster Creek are discussed in this section.

Permitted Discharges

Under TPDES, the TCEQ has issued permits to discharge treated wastewater to 15 facilities within the watershed (Table 2). All 15 are domestic wastewater (sewage) treatment facilities. Two additional facilities within the segment have been issued permits without provisions that allow discharge of wastewater—the Texas Department of Criminal Justice (TDCJ), for a confined animal feeding operation (CAFO) with land application of solid and liquid waste, and Bono Brothers Inc., for beneficial land application of sewage sludge and domestic septage. For completeness, these two facilities are also included in Table 2. Finally, Hines Nurseries has a permit for discharge of a small amount of domestic wastewater and a permit to discharge storm/irrigation waters.

From approximately 2000 to mid-2004, domestic wastewater facilities discharged a reported average of 11.9 million gallons per day (MGD) into Upper Oyster Creek, which is well below the total of 31.9 MGD allowed for all permitted discharges. A number of facilities have become operational since 2004; no monitored discharge information is provided for these facilities. Rapid urbanization of the watershed is correlated with a steadily increasing wastewater input into the segment, as indicated by increases in discharge limits for some municipal facilities within the segment and the addition of new discharge permits in recent years.

The City of Sugar Land and Fort Bend County Water Control and Improvement District (WCID) #2 permits allow the largest discharge of the wastewater facilities at over 5 MGD each. The other wastewater facilities with permitted wastewater discharges of greater than 1 MGD are Quail Valley Utility District, Missouri City, and Fort Bend County Municipal Utility Districts (MUDs) #s 25, 118, and 142. Except for the City of Missouri City, the wastewater permits do not include specific limits or monitoring requirements for indicator bacteria concentrations in their effluents. (Missouri City's permit requires monitoring because the facility uses ultraviolet light disinfection rather than chlorination/dechlorination.) With the exception of Hines Nurseries (which is permitted to discharge domestic-type waste, but does not actually do so based on self-reporting data), all permitted facilities are required to disinfect their treated effluent prior to discharge (Table 2). Disinfection is designed to reduce or eliminate bacteria from the effluent.

In 2001, TIAER staff surveyed the TPDES permit files to identify enforcement actions or other persistent problems with permitted discharge facilities within Segment 1245. Staff updated the survey in 2005 by reviewing the discharge monitoring reports (DMR) from the Permit Compliance System (PCS) downloaded from the USEPA's Envirofacts Data Warehouse (USEPA, 2005).

No enforcement actions were found in the screening. However, some self-reporting, operation, and administration violations were noted in the files. The TDCJ facility has had violations regarding uncertified personnel, operational requirements, and final effluent limitations. These violations surfaced during an annual inspection and were completely resolved within the required time frame. The TDCJ facility underwent a \$4.5 million expansion during 2001 and 2002.

Notes: ¹ Permit does not contain a discharge provision

² Pending permit as of Oct. 2, 2006 (Ft. Bend Co. MUD # 134)

³ New permit or not operational during period of dates monitored (1999-2004)

⁴ Permit also includes storm water discharge not to exceed 1.0 MGD

⁵ Concentrated Animal Feeding Operation (CAFO) general permit number

⁶ An equivalent method of disinfection may be substituted with approval from TCEQ. Only chlorination (no dechlorination) is required for facilities operating under a capacity of 1 MGD

A violation at the Missouri City facility in August 2000 is of potential relevance to this study. The facility exceeded the daily maximum, the 7-day average, and the daily average criteria for fecal coliform bacteria. The problem occurred due to an off-line aerator that had accumulated a large amount of settled solids. Solids were redistributed throughout the facility when the unit was restarted, causing poor effluent quality. The problem was resolved immediately, and subsequent fecal readings indicated no long-term concerns. No other fecal coliform effluent quality violations have been reported at the facility since that time.

Because there is a long history of efforts to improve water quality problems in Upper Oyster Creek, a number of significant changes and improvements to regulated facilities have occurred, which probably resulted in improved water quality. Kolbe (1992) reports:

- the discharge from the City of Sugar Land's wastewater treatment facility (WWTF) was moved to its present location in 1975;
- the Hines Nurseries direct discharge was removed in 1990 and reduced to storm water overflow releases; and
- wastewater treatment of the TDCJ units has improved and feedlot runoff is better managed.

In addition, changes have been made over time to mitigate the effects of the permitted discharge from the Imperial Sugar facility, which ceased any discharge into Upper Oyster Creek in 2003. After June 1996, Imperial Sugar's major discharges were delivered to the Brazos River Authority's (BRA) regional WWTF for treatment and subsequent discharge outside the watershed. Kolbe (1992) states that from 1987 through 1990, Imperial Sugar discharged an average of 17 to 21 MGD of wastewater at elevated temperature, as allowed in their permit.

For any urban collection and treatment system, sanitary sewer overflows and WWTF bypasses are possible sources of bacteria loadings to receiving waters. Concerns related to overflows and bypasses are heightened in areas with relatively high rainfall, such as the Upper Oyster Creek watershed. Because of the rapid and continuing population growth in the watershed, some of the supporting infrastructure has been built recently and has underutilized capacity, which reduces the likelihood of overflow and bypass events. Nonetheless, occurrences of such events and their subsequent impacts on bacteria loading must be recognized.

The Storm Water Phase II rule, promulgated in 1999 as part of the National Pollutant Discharge Elimination System, requires small municipalities in urbanized areas to obtain permits for their storm water systems. In Texas, Small Municipal Separate Storm Sewer Systems (MS4) will be authorized under a general permit or Phase II (Small) MS4 general permit. The permit will require affected cities and other entities to reduce their discharges of pollutants in storm water to the “maximum extent practicable” by developing and implementing Storm Water Management Programs (SWMPs). The SWMPs must specify best management practices (BMPs) for seven minimum control measures:

- public education and outreach
- public involvement/participation
- illicit discharge detection and elimination
- pollution prevention/good housekeeping
- construction site runoff control
- post-construction runoff control
- authorization for municipal construction activities

The geographic region of Upper Oyster Creek covered by the pending Phase II MS4 general permit is that portion of the watershed contained within the urbanized area determined in the 2000 Decennial Census for the greater Houston area (U.S. Census Bureau, 2000a). Much of the eastern half of the Upper Oyster Creek watershed is included in this urbanized area.

Population Density: Humans and Pets

The population of the Upper Oyster Creek watershed in 2000 was estimated to be 96,273 people (31,573 households), with an overall average population density of 877 persons per square mile (U.S. Census Bureau, 2000b). The population of Fort Bend County is estimated by the U.S. Census Bureau to have increased approximately 6 percent per year since the 2000 census, so the current watershed population may exceed 125,000. Approximately 28,000 cats and 25,000 dogs are also estimated to reside at households within the watershed, based on the 2000 census data along with national averages of pets per household from the American Veterinary Medical Association (2002).

According to the Texas Water Development Board (TWDB), Fort Bend County is expected to increase in population by approximately 78 percent from 2000 to 2020 (TWDB, 2006). As a result, the county expects significant increases in water demand for municipal purposes (65 percent increase). Smaller increases are expected for manufacturing (17 percent), mining (8 percent), and steam electric (10 percent) uses.

Table 3 sets out TWDB population growth estimates for selected cities within Fort Bend County from 2000 to 2020.

The population estimates for Sugar Land are held constant after the year 2010 because the city is expected to be completely built-out by this date. However, TWDB estimates may not account for future annexations that could occur. Annexations were used to drive the city's population growth in the 1990s. The 2000 census figures show a 158 percent increase in the population of Sugar Land since 1990.

Table 3. Fort Bend County population and projected increases by city, 2000 to 2020

City	2000 Census Population	2010 Population	2020 Population	Growth Rate (2000-2020)
Fulshear	716	883	1,056	47%
Missouri City	47,419	76,768	96,601	104%
Stafford	15,371	23,026	30,959	101%
Sugar Land	63,328	72,500	72,500	14%

Source: TWDB (2006).

Sewage Disposal

The method of sewage disposal for housing units in the Upper Oyster Creek watershed was estimated from the 1990 federal census at the block group level because these data were not collected in the 2000 census (U.S. Census Bureau, 1990). Because of rapid urbanization in the watershed, estimates based on those data may no longer be accurate. At that time, approximately 7 percent of households (about 1,400 units) were not connected to a sanitary sewer system (the majority of those utilized septic tanks for sanitary waste disposal), while 93 percent were connected to a sanitary sewer system.

The more rural western half of the watershed was primarily served by septic tanks. However, the highest density of septic tanks was in two areas:

- the Fifth Avenue area southeast of Stafford and northwest of Missouri City, bounded roughly by Cartwright Road on the south, American Canal on the north and east, and farm-to-market (FM) Road 1092 on the west.
- the Four Corners area northwest of Sugar Land, bounded by SH 6 on the east, Old Richmond Road on the west, Voss Road on the south, and Boss-Gaston Road on the north.

The density of septic tanks in these two areas was approximately 0.3 per acre.

Livestock Populations

The smallest unit for which livestock census data are available is the whole of Fort Bend County, which show beef cattle to be the dominant livestock species in the watershed (Table 4). Other livestock species present in the watershed include horses, goats, chickens, and hogs. Livestock populations were estimated from the 2002 agricultural census of the National Agricultural Statistics Service of the U.S. Department of Agriculture (USDA), or from more recent estimates of the Texas Agricultural Statistics Service, when available.

Table 4. Estimated livestock populations in Fort Bend County

Livestock	Fort Bend County	Estimated Watershed Population ^{††}
Cattle & Calves-All	51,000 [†]	6,375
Horses	3,400 [‡]	425
Mules, burros, & donkeys	116 [‡]	14

^{††} Based on watershed comprising 12.5% of county.

Wildlife and Feral Animals

An initial sanitary survey to identify potential bacteria sources within the Upper Oyster Creek watershed was performed from May 3 to 5, 2004. Note that this survey was not designed to quantify or estimate the population sizes of wildlife or feral animals, and that many additional observations of these animals (as well as fecal collections) took place over nine months of sampling in 2004. The most evident feces observed adjacent to water bodies in urban areas were from waterfowl, specifically ducks and geese. A large number of Muscovy ducks, a non-native resident, were observed in central portions of the watershed, particularly in the many residential lake areas. Duck fecal matter was very dense along the banks of impounded Upper Oyster Creek at Fluor-Daniel Road. Black-bellied whistling-ducks (a native species) were also observed to defecate at this same location.

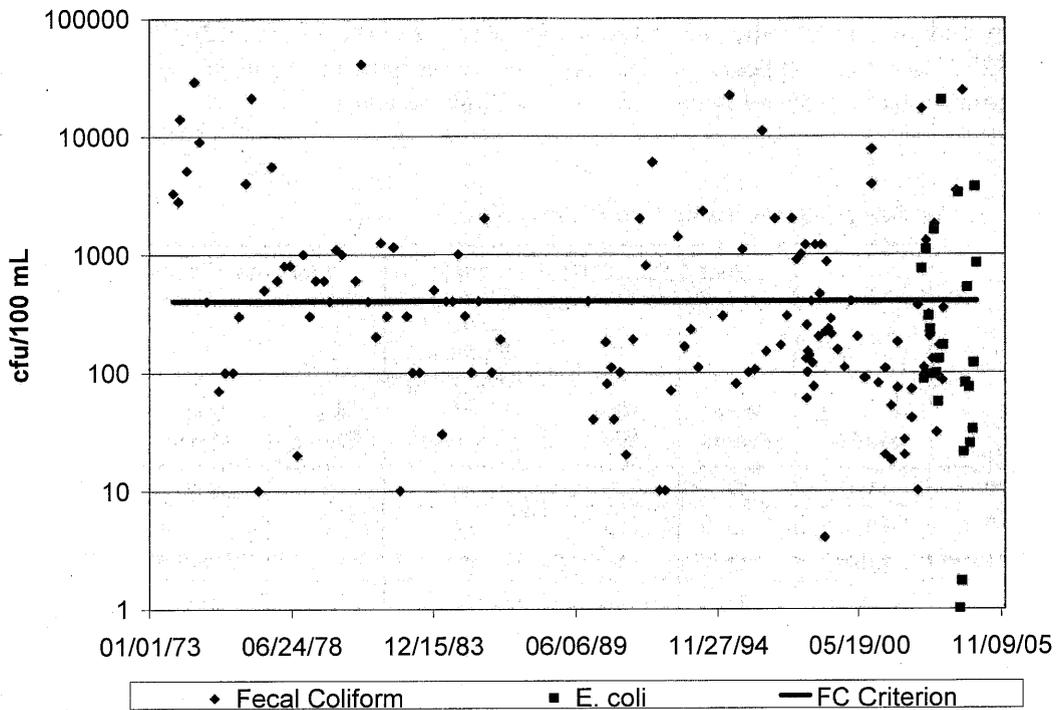

Pigeons and various species of swallows were observed to be nesting on bridges over Oyster Creek at a number of locations, and perching on utility lines over the creek. Their dried fecal matter caked portions of the bridges. The swallows were only observed during the summer months. Other common birds in and near the creeks included several species of herons and egrets.

In rural areas, raccoon feces were frequently observed, especially adjacent to smaller, more sheltered waterways. During the March sampling event, the raccoon diet appeared to consist mostly of blackberries, but crayfish parts littered the banks of these smaller water bodies as well. Road kill indicated the expected fauna of southeast Texas, including skunks, raccoons, armadillos, and opossum. Local residents also commented that feral hogs are common in parts of the Upper Oyster Creek watershed.

Linkage Analysis

Establishing the relationship between instream water quality and the source of loadings is an important component in developing a TMDL. It allows for the evaluation of management options that will achieve the desired endpoint. The relationship may be established through a variety of techniques. This TMDL makes use of the load duration curve approach. The method has found relatively broad acceptance among the regulatory community, because of the simplicity of the approach and ease of application. The load duration curve approach provides a means to determine loading relationships, reductions, allocations, and possible sources at a broad level. It is discussed in much greater detail in the "Pollutant Load Allocation" section later in the document.

As a precursor to linking the potential sources of bacteria mentioned in the preceding section to Upper Oyster Creek, additional sampling was conducted to determine the severity and extent of the bacteria impairment. The TCEQ and its predecessor agencies have collected limited data for decades, particularly at Station 12083, located in the lakes region in Sugar Land. Figure 3 shows that high bacteria counts have been measured often at this station since the early 1970s. Despite this relatively long record for Station 12083, fecal coliform data were usually collected only quarterly, with gaps that sometimes stretched for several years at a time.

The single sample criterion used here is for fecal coliform [400 cfu/100 mL] since that bacteria accounts for the bulk of the historical data. The criterion for *E. coli* (394 cfu/100 mL) is not shown, since it would be indistinguishable from the fecal coliform criterion at the logarithmic scale used in this graph.

Figure 3. Bacteria Data for Station 12083, including single sample standard

For the TMDL, additional *E. coli* sampling began in October 2002 and continued through November 2004. Two sampling programs were conducted for two different purposes. In Year 1 (October 2002 through August 2003), 12 surveys were performed approximately monthly to provide the data necessary to assess *E. coli* levels in Upper Oyster Creek. In Year 2 (from March 2004 through November 2004), 12 additional surveys were performed at selected stations with the intent of sampling to allow the capture of some rainfall-runoff events, which provide biased sampling not appropriate for assessment purposes. The later surveys were conducted as part of a bacterial source tracking study. Under the assessment surveys conducted from October 2002 through August 2003, sampling stations were located throughout the segment (including some tributaries and off-channel lakes) to give insight into the spatial distribution of the bacteria load in Upper Oyster Creek (Figure 4).

The assessment survey for Year 1 (October 2002 – August 2003) showed *E. coli* exceeded the criteria for both geometric mean and single sample criteria through much of Upper Oyster Creek and its tributaries (Table 5 and Figure 4). The only areas where concentrations were consistently below the criteria were:

- the station just downstream from the GCWA pumping station on the Brazos River (Station 17685), and
- in and just below the lakes region (Stations 11510, 17686, 12079, 17373, and 12077), which appears to be because of enhanced bacteria settling due to conditions of reduced water velocities within the lakes.

Table 5. *E. coli* Sampling Results for Upper Oyster Creek

	Station	Year 1 (Oct. 2002–Aug. 2003)			Year 2 (Mar. 2004–Nov. 2004)

	17690	12	417	50			

¹ SS criterion is the single sample criterion. TCEQ applies the binomial method to establish the required number of exceedances to indicate nonsupport of the contact recreation use. To determine nonsupport (*i.e.*, greater than 25 percent of samples exceed the criterion) and to keep the percent probability at less than 20 percent of inappropriately assessing Upper Oyster Creek as not supporting when it is actually fully supporting, a minimum of five samples must be in exceedance for a sample size of 12—an exceedance of 42 percent.

In contrast, data collected in or just downstream of two major tributaries—Flewellen Creek—Station 17686 and Stafford Run—Stations 17688 and 12075—showed *E. coli* counts that were significantly higher than average. Another tributary, Red Gully—Station 11516—had lower *E. coli* numbers, which is attributed to chlorinated effluent from two small (less than 1 MGD) municipal wastewater treatment plants that reduce instream bacteria levels during low flows.

Bacterial Source Tracking

This TMDL project employed a bacterial source tracking (BST) method referred to as manual ribotyping, performed at the laboratories of the Institute for Environmental Health, Inc. in Seattle, Washington. The BST study involved three steps:

- collecting bacterial (in this case *E. coli*) isolates from fecal samples of known origin to create a watershed-specific library;
- collecting water samples (under both runoff and non-runoff conditions) from which fecal bacteria of unknown origin were cultured; and
- employing a genotypic-based method to compare method-specific characteristics of bacteria from the water to the same characteristics of the bacteria in the library. Since the bacteria are considered to be generally host-specific, exact matches of characteristics implicate a particular animal species (or group of related animals) as the contributor of that bacterial strain in the unknown sample collected from the ambient water.

The preliminary results of the BST study confirmed that the bacteria in Upper Oyster Creek come from a variety of sources, including humans, pets, livestock, and wildlife (avian and mammalian). No particular source group dominated any of the sampling stations (TIAER, 2006). The BST results provided qualitative information that did not modify the allocations presented in this TMDL, but will likely be used more extensively during the implementation phase of this project. At that time a broad array of control measures targeted to specific sources will need to be considered.

Seasonal Variation

Both high and low *E. coli* measurements were observed throughout the year. This observation suggests a lack of seasonality for bacteria in Upper Oyster Creek. However, bacteria levels in Upper Oyster Creek are clearly tied to rainfall-runoff events. In that sense, it is reasonable to assume that wetter parts of the year are more likely to have exceedances of the water quality standards. In Table 6, the *E. coli* data from the second year of the study are separated into runoff and non-runoff events. A sampling event was considered to be influenced by runoff if more than one-quarter inch of rain was measured at the Sugar Land Regional Airport on the day of sampling (before the sample was collected) or on the previous day. Without exception, the sampling from the runoff events resulted in much higher *E. coli* counts.

Margin of Safety

The margin of safety (MOS) is designed to account for any uncertainty that may arise in specifying water quality control strategies for the complex environmental processes that affect water quality. Quantification of this uncertainty, to the extent possible, is the basis for assigning an MOS. The MOS provides a higher level of assurance that the goal of the TMDL will be met. The MOS may be incorporated using two methods:

- implicitly incorporating the MOS using conservative model assumptions to develop allocations; or
- explicitly assigning a loading amount for the MOS.

Table 6. *E. coli* Sampling Results in Runoff vs. Non-Runoff Conditions

	Station	Runoff Conditions			Non-Runoff Conditions		
		Number of Events	Geo. Mean	Percent Samples Exceeding SS Criterion ¹	Number of Events	Geo. Mean	Percent Samples Exceeding SS Criterion ¹
Upstream  Downstream	17685	2	3,913	100%	2	33	0%
	17686	2	12,411	100%	2	76	0%
	12090	5	4,165	100%	7	135	17%
	12087	3	3,392	100%	9	121	18%
	11516	2	10,871	100%	2	4	0%
	12086	3	6,265	100%	9	75	11%
	12083	3	2,355	100%	9	41	11%
	17688	3	8,565	100%	9	356	42%
12074	3	3,509	100%	9	157	36%	

¹ SS Criterion is Single Sample Criterion

This TMDL uses an implicit MOS. The bacteria load allocation is based on the difference between the load duration curve of the single sample criterion and the exponential regression line through sampled data that exceed the criterion for each of the six stations used in this analysis (see the “Pollutant Load Allocation” section). The exponential regression line based on the exceedances gave a reasonable representation of existing bacteria loadings for those monitored periods when contact recreation was not supported.

Using only data that exceeded the single sample criterion to develop the exponential regression line provides an implicit margin of safety, since *E. coli* concentrations with values ≤ 394 cfu/100 mL were measured with relatively high frequency at each of the six stations but were not included in the analysis. Additionally, the state’s water quality assessment methodology provides a further implicit margin of safety because it specifies that the contact recreation use is still supported when 25 percent or less of the individual samples exceed the single sample criterion (TCEQ, 2003); the data for these allowable exceedances were not factored into the load reduction analysis.

Pollutant Load Allocation

The TMDL represents the maximum amount of pollutant that the stream can receive in a single day without exceeding the water quality standard. The load allocations for the selected scenarios are calculated using the following equation:

$$\text{TMDL} = \sum \text{WLA} + \sum \text{LA} + \text{MOS}$$

Where:

WLA = wasteload allocation (point source contributions)

LA = load allocation (nonpoint source contributions)

MOS = margin of safety

Typically, there are several possible allocation strategies that would achieve the TMDL endpoint and water quality standards. Available control options depend on the number, location, and character of pollutant sources.

The pollutant load allocation for the Upper Oyster Creek bacteria TMDL was performed using a hybrid approach, using load duration curves with a mechanistic hydrologic watershed model (TIAER, 2006). The pollutant load allocation involved several steps:

- development of load duration curves
- definition of allocation reaches
- analysis of load reductions
- analysis of geometric mean criterion analysis
- allocation process
- future growth and other considerations

Each of these steps is discussed in the following section.

Development of Load Duration Curves

The load allocation tool selected for this TMDL is the load duration curve method with the necessary hydrologic information provided by the Soil and Water Assessment Tool (SWAT; Arnold et al., 1998). The absence of recent, long-term daily streamflow data for any location on Upper Oyster Creek and the complexities of the watershed's hydrology (e.g., water pumping from the GCWA, small dams, flood control practices, and several wastewater treatment plant discharges) necessitated that a mechanistic watershed hydrologic model, in this application SWAT, be used to develop the necessary daily streamflow data at several locations in the Upper Oyster Creek system (TIAER, 2006). Based on availability of daily pumping records from the GCWA for the period 1993–2004, this 12-year period was selected to define the hydrologic record used in the developing the duration curves. The period 1993–2004 is sufficiently long to include a reasonable variety of weather conditions and hydrologic responses (e.g., high and low rainfall periods).

Using the calibrated SWAT2003 model of Segment 1245, simulated daily streamflow data for 1993–2004 were combined with existing *E. coli* data to develop the bacteria load duration curve tool for desired locations in the watershed. Six stations were selected for

development of load duration curves based on availability of sufficient *E. coli* data: 12074, 17688, 12083, 12086, 12087, and 12090 (Figure 4). The following steps were undertaken to develop the desired bacteria load duration curves.

Step One

The predicted daily streamflow data for 1993–2004 at each of the six selected stations were obtained as model output. The daily data were used to develop a flow duration curve for each station. The flow duration curve was generated by:

- 1) ranking the daily flow data from highest to lowest,
- 2) calculating the exceedance value for each ranked daily flow (rank ÷ number of data points), and
- 3) plotting each flow value (y-axis) against its exceedance value (x-axis).

Step Two

In the next step, the flow duration curve was combined with the pertinent numeric water quality criterion (the single sample criterion in this case) to develop a load duration curve for that criterion. The single sample criterion is defined as an *E. coli* concentration not to exceed 394 cfu/100 mL. The load duration curve was calculated by multiplying each ranked flow (obtained in Step One) by the *E. coli* criterion (394 cfu/100 mL) and by the conversion factor (8.64×10^8), giving units of colonies per day.

Step Three

For each station, each existing *E. coli* measurement was associated with the predicted streamflow on the day of that measurement. The bacteria measurement and predicted flow measurement were then converted to a bacteria loading in units of colonies per day (using the same method described in Step Two for expressing the bacteria criteria as loadings). The associated daily streamflow for each daily bacteria loading was then compared to the flow duration curve data to determine its value for “percent days flow exceeded.” Each existing loading was then plotted on the load duration curve at its percent exceedance. This process was repeated for each *E. coli* measurement at each station.

Points above a curve represent exceedances of that bacteria criterion and its associated allowable loadings. To provide as much data as possible for developing the analysis, *E. coli* data were combined from both the October 2002 through August 2003 assessment effort and the March through November 2004 BST study.

The flow duration curve and the *E. coli* load duration curve with the single sample exceedance line shown are provided in Figures 5–10 for stations 12074, 17688, 12083, 12086, 12087, and 12090, respectively. The flow duration and corresponding load duration curves for stations 12083, 12086, 12087, and 12090 (Figures 7–10) reflect a shape highly influenced by the GCWA pumping at the Shannon and Second Lift Stations, which results in the relatively constant flows between 1 and 8 m³/s that occur about 70 percent of the time.

Stations 12074 and 17688 (Figures 5 and 6), which are outside the influence of the pumping, had flow duration curves with shapes typical of streams in which flow is not as heavily dominated by large amounts of nearly constant pumped flows. The flow duration curves for both stations do, however, show the influence of continuous discharges from municipal WWTFs. Flows at these stations are typically below about 0.2 m³/s.

Definition of Allocation Reaches

For purposes of performing load reduction analysis, Upper Oyster Creek was separated into two distinct hydrologic reaches. As previously presented in this report (see “Watershed Overview”), the portion of Upper Oyster Creek above Dam #3 serves as conveyance for water pumped by the GCWA from the Brazos River (see Figure 1) and annually diverts approximately 50,000 acre-feet of Brazos River water.

Much of the creek below Dam #3 has characteristics of a typical southeast Texas urban/suburban creek including modifications to reduce flooding potential and enhancements to speed water conveyance. Based on these hydrological distinctions, Upper Oyster Creek was divided into two allocation reaches for this bacteria load reduction analysis (Figure 17 in the section “Allocation Process” shows the areas of the reaches along with other details).

- **Allocation Reach 1:** Segment 1245 from its downstream confluence with the Brazos River up to Dam #3.
- **Allocation Reach 2:** Segment 1245 from Dam #3 up to the GCWA Shannon Pump Station.

While portions of both allocation reaches contain monitoring stations where data indicate support of contact recreation (see Table 5), *E. coli* levels are elevated throughout most of the length of Segment 1245. Therefore, to ensure the desired bacteria load reductions are achieved throughout the entire watershed, the two allocation reaches make up the entire length of the segment.

Load Reduction Analysis

For each allocation reach, a percent load reduction was determined using the differences between the loadings (represented by an exponential regression line) and the single sample criterion at each of the six stations for which load duration curves were developed. The following steps were used to determine the percent reduction by allocation reach:

- 1) Obtain the load duration curves by station for each reach. For Allocation Reach 1, stations 12074 and 17688 were used. For Allocation Reach 2, stations 12083, 12086, 12087, and 12090 were used.
- 2) For each station, develop an exponential regression line through relevant *E. coli* data points to characterize the existing loading of bacteria (Figures 11-16). Data considered relevant for determining the regression line were those at concentrations that exceeded the single sample criterion and also occurred at a flow exceeded on more than 0.27 percent of days (or on average, occurring at a flow exceeded more than one day per year).

By happenstance, the bacteria sampling events on November 2 and 23, 2004, occurred during periods of high rainfall, and at several stations, these events produced data points that had a very small exceedance percentage (<0.27 percent). These data points became "leverage" points in the exponential regression, which increased the downward (left to right) slope of the regression at these stations. Removal of the data points for the two November sampling events provided a regression line that more closely fit through more of the relevant data points, thus better reflecting the existing loading that exceeded the single sample criterion.

- 3) For each station, determine the required percent removal at 5 percent intervals along the x-axis (*i.e.*, 5 percent intervals of days the loading was exceeded). The extreme high-flow interval was defined at 1 percent, which represented a reasonably extreme event occurring three or four days a year, on average.

Thus, the first interval was defined as 1 percent, the next as 5 percent, and then at 5 percent intervals thereafter. Intervals were restricted to either the closest 5 percent interval near the last *E. coli* data point that exceeded the criterion or to the last 5 percent interval that had an associated positive load reduction (*i.e.*, where the regression line lies above the criterion line). This restriction was necessitated by the paucity of *E. coli* data with associated low daily streamflows for which loadings were exceeded greater than 70 percent of days. Collectively, these refinements allowed determination of percent reduction for load duration curves by station in both allocation reaches for the range of streamflow conditions under which bacteria exceedances occurred (Table 7).

- 4) For each station, the required load reduction to meet the single sample criterion was calculated as the arithmetical average of the percent reductions at the defined intervals derived in step 3 (Table 7).
- 5) As the final step, the required load reduction in both allocation reaches was calculated as the average of the percent reductions determined in step 4.

Averaging the percent load reductions in Allocation Reach 1 yielded a value of 73 percent. Likewise, averaging the four stations in Allocation Reach 2 also yielded a value of 73 percent.

Therefore, the percentage reduction in loads of *E. coli* required to meet the single sample criterion are as follows:

- **Allocation Reach 1**: 73 percent
- **Allocation Reach 2**: 73 percent

The fact that the load reductions calculated for both reaches are the same is coincidental.

Geometric Mean Criterion Analysis

Though the primary endpoint for this bacteria TMDL is the single sample criterion, the geometric mean criterion was considered a secondary criterion that should also be met in order for Segment 1245 to fully support its contact recreation use. In both allocation reaches, when the average reduction of 73 percent was applied to the combined dataset (all stations with existing *E. coli* data not supporting contact recreation), the results indicated that *E. coli* concentrations would be at or below the geometric mean criterion (Table 8). The calculated value for Allocation Reach 1 is equivalent to the geometric mean criterion concentration of 126 cfu/100 mL, while the calculated value for Allocation Reach 2 is 76 cfu/100 mL. Therefore, the required load reduction to achieve the single sample criterion should also achieve the geometric mean criterion in both reaches.

Existing Loads

For each allocation reach, the existing daily *E. coli* loading was estimated using data from the most downstream station for which the load reduction analysis was performed—Station 12074 for Allocation Reach 1 and Station 12083 for Allocation Reach 2. By selecting the most downstream station, the greatest amount of each allocation reach was included, based on data availability.

The exponential regression line through *E. coli* data points that exceeded the single sample criterion was the basis for estimating existing loadings. Existing loadings were estimated by averaging the daily loadings from the exponential regression line over the entire range of flows (i.e., exceedances from 1 % to 99 %) (Table 9). This method of estimating the existing loading is accepted when using load duration curves, and also provides an implicit margin of safety as discussed previously (see the “Margin of Safety” section). Based on this approach, the following average daily loadings were estimated:

- **Allocation Reach 1:**
existing daily average *E. coli* loading = 4,570 billion cfu per day
- **Allocation Reach 2:**
existing daily average *E. coli* loading = 7,492 billion cfu per day

Allocation Process

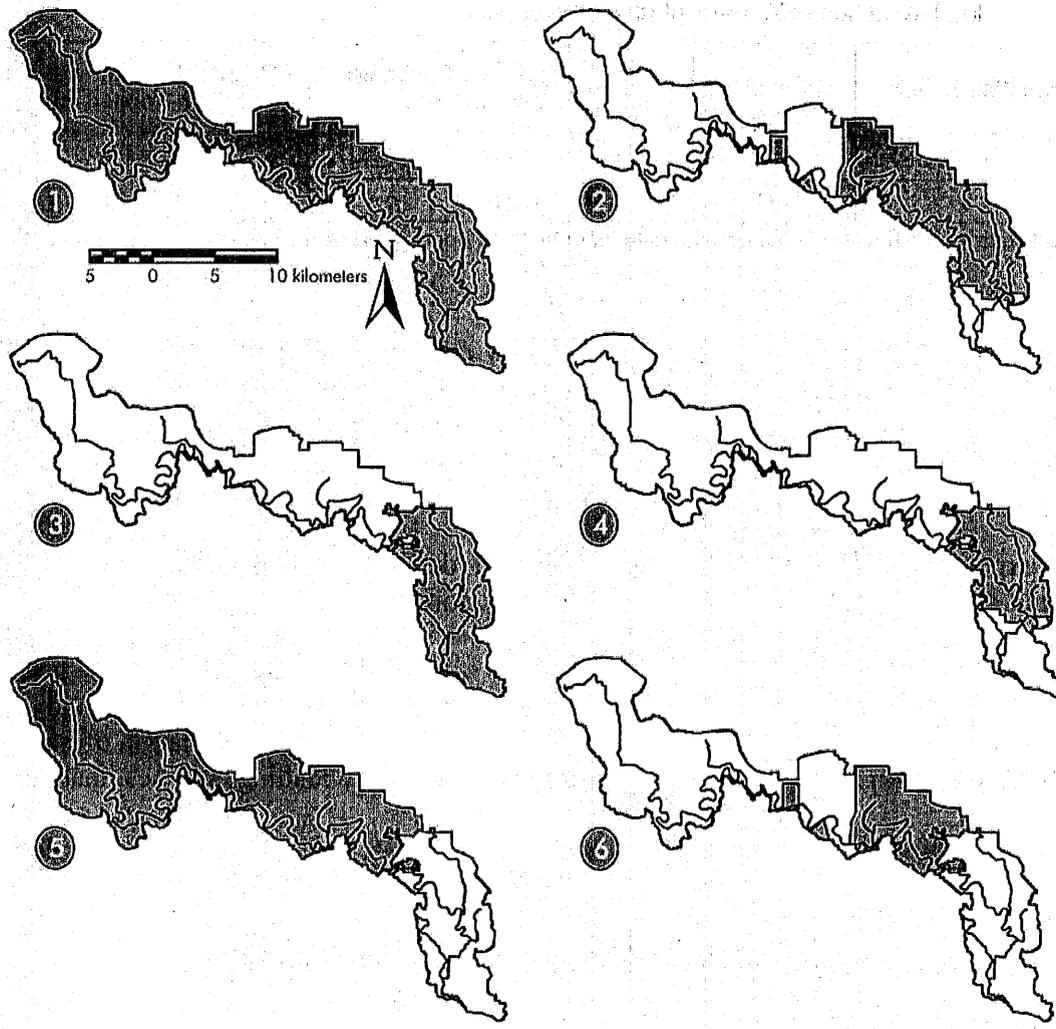

The TMDL load allocation for Segment 1245 was performed to account for the pending general permit for Small Municipal Separate Storm Sewer Systems (Phase II MS4s), which will provide authorization for storm water discharges which are already occurring, but not currently permitted.

The geographic region of Segment 1245 that will be covered by the Phase II MS4 general permit is that portion of the watershed contained within the urbanized area defined in the 2000 Census for the greater Houston vicinity (see Figure 17). Approval of the general permit (and subsequent applications from dischargers) is expected to occur in 2007.

TMDL Allocation for Allocation Reach 1

The allowable loading of *E. coli* that Allocation Reach 1 can receive on an average daily basis was determined using:

- the single sample criterion load duration curve for station 12074 (Figure 11), and
- the same percent exceedance intervals used to estimate the existing loading.

	Area (ha)

TIAER
UpperOysterCr06OCT2006.pdf

Figure 17. Upper Oyster Creek showing allocation reaches and urbanized area

The average maximum allowable daily loading determined from the load duration curve was increased to reflect the additional loading that would originate from the difference between loadings if WWTFs operated at their full allowable daily discharges and the loadings that would be allowable under the average WWTF discharges reported for years

2000-2004. With the additional loading included, the maximum allowable daily average loading is estimated at 1,453 billion cfu per day (Table 9). The reason for including this additional load follows.

99	2	77	1,680	0
Average	4,570	1,253	7,492	1,602
Additional Loading ¹	—	200	—	80
Total	—	1,453	—	1,682

¹ Additional loading is the increase in allowable *E. coli* loading from the existing discharge condition of WWTFs used to develop the single sample criterion load duration curve to the allowable loading for the final permitted discharge from WWTFs.

The daily streamflow record used in developing the load duration curve for the single sample criterion was based on recent discharge information from permitted discharge facilities, and this information was used as input in the SWAT model (see TIAER (2006), Section 4 for more details). However, the TMDL allocation must be based on the full allowable discharge for each facility, not the recent discharges, to account for increased loadings that may occur if or when facilities discharge at their maximum allowable levels.

In Allocation Reach 1, the combined allowable discharge of all facilities is 24.602 MGD (as shown in more detail later in this section). The recent combined discharge averaged 11.204 MGD, resulting in a difference between recent and allowed discharges of 13.398 MGD. Because this allowable increase in discharge and the associated allowable loading would be continuous (*i.e.*, would apply equally to all days of each year regardless of streamflow), the difference between the two discharge rates multiplied by the single sample criterion is the additional allowable loading, as reflected at the bottom of Table 9. The computed, additional allowable bacteria loading for the 13.398 MGD, at an assumed rate equal to the single sample criterion concentration of 394 cfu/100 mL, is 200 billion cfu per day.

Wasteload Allocation (Continuous) for Allocation Reach 1

Seven municipal wastewater treatment plants operate within Allocation Reach 1. Several of these facilities operate under a phased permit that allows progressively higher daily average discharges as facility expansions are made in response to anticipated growth. The final and largest discharge for each facility was used in the load allocation process. A list of the seven facilities and their final allowable daily average discharges follows.

- | | |
|--|-----------|
| 1) City of Missouri City (WQ0013873-001) | 3.0 MGD |
| 2) City of Sugar Land (WQ0012833-002) | 10.0 MGD |
| 3) Fort Bend Co. WCID # 2 (WQ0010086-001) | 6.0 MGD |
| 4) Palmer Plantation MUD # 1 (WQ0012937-001) | 0.60 MGD |
| 5) Quail Valley UD (WQ0011046-001) | 4.0 MGD |
| 6) Sienna Plantation MUD # 1 (WQ0014100-001) | 0.902 MGD |
| 7) Stafford Mobile Home Park (WQ0014064-001) | 0.10 MGD |

The combined permitted discharge from these facilities is 24.602 MGD. The maximum allowable *E. coli* concentration for each of these facilities is assumed to be the single sample criterion (394 cfu/100 mL). The combined discharge and single sample criterion were multiplied together, yielding a WLA for continuous discharges of 367 billion cfu per day. However, based on the requirements in permits for disinfection and the limited bacteria data available for effluents from permitted facilities in the Upper Oyster Creek watershed (*i.e.*, City of Missouri City in Allocation Reach 1 and Fort Bend Co. MUD #25 in Allocation Reach 2), these treatment facilities are routinely expected to discharge well below the allowable single sample criterion.

Load Allocation and Non-Continuous WLA for Allocation Reach 1

The remaining allowable load was computed by subtracting the WLA from the allowable TMDL, yielding a total of 1,086 billion cfu per day. This was separated into two components: the urbanized area that is expected to be included under the Phase II MS4

general permit (“WLA Non-continuous”) and the LA, which consists of all non-regulated, nonpoint sources. Note that for this document, the WLA Non-continuous also includes permitted storm water components from construction sites and certain industrial activities, as well as “allowable non-storm water” discharges defined by the pending Phase II MS4 general permit. This applies to both allocation reaches.

The drainage area of Allocation Reach 1 includes 7,522 hectare (ha), of which 4,843 ha are within the urbanized area. To divide the remaining load between the urbanized area and the LA category, the urbanized area was computed as the ratio of its area to the total drainage area: $4,843 / 7,522 = 0.6438$). In a similar manner, the LA category was computed $(7,522-4,843) / 7,522 = 0.3562$). Multiplying the total allowable load by the appropriate area ratios yields a WLA Non-continuous for the urbanized area of 699 billion cfu per day, and an LA of 387 billion cfu per day.

The total load allocation for Allocation Reach 1 with the Phase II MS4 general permit is provided in Table 10. The total WLA is 1,066 billion cfu per day and the total LA is 387 billion cfu per day.

Table 10. TMDL allocation summary for Allocation Reach 1

Allocation Reach	TMDL	WLA Continuous	WLA Non-continuous	LA Other	MOS
(all units in billion cfu per day)					
1	1,453	367	699	387	Implicit

TMDL Allocation for Allocation Reach 2

The allowable loading of *E. coli* that Allocation Reach 2 of Upper Oyster Creek can receive on an average daily basis was determined using:

- the single sample criterion load duration curve for station 12083 (Figure 13), and
- the same percent exceedance intervals used to estimate the existing loading.

As was required for Allocation Reach 1, the average maximum allowable daily loading determined from the load duration curve was increased to reflect the additional loading that would originate if WWTFs operated at their allowable daily discharges rather than at their recent discharges.

The combined allowable WWTF daily discharge for facilities in Reach 2 is 6.2785 MGD. The recent combined discharges were 0.9292 MGD (used in the SWAT model). The combined allowable additional loading is 5.3493 MGD (6.2785 – 0.9292). Using the assumed single sample criterion concentration of 394 cfu per day, the additional bacteria loading would be 80 billion cfu per day. Adding this increase gives an adjusted maximum allowable daily average loading of 1,682 billion cfu per day (Table 9).

Wasteload Allocation (Continuous) for Allocation Reach 2

Eight domestic wastewater treatment plants operate, or are in the process of being permitted to operate, within Allocation Reach 2. Several of these facilities operate under phased permits, which allow progressively higher daily average permitted discharges as facilities expand in response to anticipated growth. The final and largest discharge for each facility was used in the load allocation process. The eight facilities and their final allowable daily average discharges follow.

1) Fort Bend Co. MUD # 25 (WQ0012003-001)	1.6 MGD
2) Fort Bend Co. MUD # 41 (WQ0012475-001)	0.86 MGD
3) Fort Bend Co. MUD # 118 (WQ0013951-001)	1.2 MGD
4) Fort Bend Co. MUD # 134 (WQ0014715-001)	0.30 MGD
5) Fort Bend Co. MUD # 142 (WQ0014408-001)	1.2 MGD
6) Fort Bend Co. MUD # 182 (WQ0014692-001)	0.80 MGD
7) Hines Nurseries (WQ003015-000)	0.0035 MGD
8) TDCJ Jester Unit # 1 (WQ0011475-001)	0.315 MGD

The combined allowable discharge from these facilities is 6.2785 MGD. The allowable *E. coli* concentration for each of these facilities is assumed to be the single sample criterion (394 cfu/100 mL). The WLA from regulated continuous discharges is estimated to be 94 billion cfu per day (the combined allowable discharge multiplied by the single sample criterion for *E. coli*).

Load Allocation and Non-Continuous WLA for Allocation Reach 2

The remaining components in the computation of the TMDL allocation include the Non-continuous WLA and the LA. Because of the nature of sources in Allocation Reach 2 and the complicating factor of the GCWA's pumping of Brazos River water into the reach, these remaining components were computed in a progressive manner, as explained in the next paragraphs.

The bacteria loading from GCWA pumping of Brazos River water was included as a portion of the LA. The bacteria contribution of the pumped water throughout Allocation Reach 2 is difficult to estimate due to the extremely dynamic response of *E. coli* to die-off, settling, and other processes. The allowable load from the Shannon Lift Station pumping was determined using the average daily pumping rate at the lift station (2.05 m³/s) and the geometric mean *E. coli* concentration (75 cfu/100 mL) that was measured at station 17685 (Jones Creek at Bois D'Arc Lane; Figure 4 and Table 5) during October 2002 through August 2003. The computed loading is 133 billion cfu per day. The geometric mean concentration was used rather than the single sample criterion to reflect the fact that observed *E. coli* concentrations in water pumped from the Brazos River were typically lower than the criteria.

As in Allocation Reach 1, portions of the drainage area of Allocation Reach 2 are within the urbanized area defined in the 2000 Census that will be included within the Phase II MS4 general permit. The drainage area of Allocation Reach 2 includes 20,110 ha, of which 5,168 ha are within the urbanized area.

Two other complexities to the developing the load allocation exist in the watershed of Allocation Reach 2. First, Hines Nurseries has a storm water permit in addition to its wastewater discharge permit, the latter of which is already included under the Continuous WLA component. Second, Bono Brothers Inc. and the TDCJ's Jester Unit CAFO each have permits that do not provide for discharge, but do allow use of agricultural lands for the beneficial land application of organic wastes. These three permitted facilities were included within the non-continuous WLA category, and their allowable loading was estimated based on their combined operational areas of approximately 451 ha.

An area ratio procedure similar to that used for Allocation Reach 1 was used to separate the allowable load in Reach 2 into the two components of LA and "WLA Non-continuous." The loading to be allocated to these two components is 1,455 billion cfu per day, which is equal to the total allowable loading (1682) minus both the Continuous WLA (94) and the GCWA pumping load (133). After the area ratio computations were completed, the additional loading from the GCWA pumping was added to the LA.

The following area ratios were used in the computation of the remaining TMDL loadings:

- WLA Non-continuous: $(451 + 5,168) / 20,110 = 0.2794$
- LA $(20,100 - 5,168 - 451) / 20,110 = 0.7206$

Multiplying 1,455 billion cfu per day by the appropriate area ratio and adding the previously computed allowable GCWA load to the LA category provides:

- WLA Non-continuous load of 407 billion cfu per day
- LA load of 1,181 billion cfu per day

The total load allocation for Allocation Reach 2 with the Phase II MS4 general permit is provided in Table 11. The total WLA is 501 billion cfu per day and the total LA is 1,181 billion cfu per day.

Table 11. TMDL allocation summary for Allocation Reach 2

Allocation Reach	TMDL	WLA Continuous	WLA Non-continuous	LA Other	MOS
(all units in billion cfu per day)					
1	1,682	94	407	1,181	Implicit

Future Growth

Because of the rapid urbanization of much of the Upper Oyster Creek watershed, additional increases in permitted discharges for treating domestic wastes are expected. In accordance with this bacteria TMDL, any new permitted discharges and any additional increases in permitted daily flow for existing facilities will be held to the same bacteria criteria used in this allocation process. The disinfection requirements on existing

facilities are expected to meet the ambient stream criteria for bacteria in Segment 1245. Therefore, the effluent of any additional permitted facilities should not result in nonsupport of the contact recreation use. At worst, additional discharges should result in a neutral impact on Segment 1245 by increasing streamflow while adding bacteria at concentrations meeting protective criteria. Because of disinfection requirements in their permits, existing and future facilities are typically expected to discharge at concentrations less than the bacteria criteria. As a means of providing reasonable assurance that permit requirements are being met, various methods may be employed to determine that discharges are meeting these criteria. Options could include TCEQ inspections and monitoring of WWTF effluent, routine monitoring by WWTFs (at a frequency and duration to be determined during the implementation phase of the project, if deemed necessary), routine examination of self-reporting data for chlorine residuals, or other methods.

The rapid urbanization in Upper Oyster Creek watershed will change land uses in addition to increasing permitted discharges. Urban lands will increase and agricultural and rural lands will decrease. Relative contributions to bacteria loadings by different sources would also change, though it is not possible to reasonably estimate whether bacteria loadings to Upper Oyster Creek will increase or decrease. Bacteria control practices may need to be adjusted in the future to respond to these changing conditions.

Summary of the TMDL Allocation

The load duration curve method was used to develop the load allocation for Upper Oyster Creek (Segment 1245). Because of distinct hydrologic differences, Segment 1245 was separated into two allocation reaches:

- **Allocation Reach 1:** Segment 1245 from its downstream confluence with the Brazos River up to Dam #3.
- **Allocation Reach 2:** Segment 1245 from Dam #3 up to the GCWA Shannon Pump Station.

An implicit margin of safety was used in calculating the TMDL based on the use of the exponential regression line through measured *E. coli* data exceeding the single sample criterion of 394 cfu/100 mL. The calculated percent reduction required to meet the allowable loading for the single sample criterion also meets the geometric mean criterion in both allocation reaches. The TMDL allocations for both reaches with Phase II MS4 general permit conditions are summarized in Table 12.

Note that if a final percentage load reduction is calculated using the existing and allowable loading values shown in Table 12, the results will be different from the final reductions of 73 percent calculated for both reaches in the section "Load Reduction Analysis" (see Table 7). There are two reasons for this difference. First, the final percent reduction for each allocation reach was based on the average for two or more locations (stations) within each reach to ensure an average percent reduction that will achieve support of the contact recreation use along the entire length of the reach, rather than at just one location. Second, the final percent reduction for each station was computed as the average of the individual percent reductions calculated at 5 percent increments. In

contrast, the load allocations were determined for the most downstream station in each reach so that the greatest amount of each allocation reach was included, based on data availability.

Table 12. TMDL allocation summary for Allocation Reaches 1 and 2 of Upper Oyster Creek

Allocation Reach 1	
Existing Loading	4,570 billion cfu/day
Allowable Loading	1,453 billion cfu/day
Waste Load Allocation (Continuous)	367 billion cfu/day
Waste Load Allocation (Non-continuous)	699 billion cfu/day
Waste Load Allocation (Total)	1,066 billion cfu/day
Load Allocation	387 billion cfu/day
Margin of Safety	Implicit
Required Percent Reduction	73 %
Allocation Reach 2	
Existing Loading	7,492 billion cfu/day
Allowable Loading	1,682 billion cfu/day
Waste Load Allocation (Continuous)	94 billion cfu/day
Waste Load Allocation (Non-continuous)	407 billion cfu/day
Waste Load Allocation (Total)	501 billion cfu/day
Load Allocation	1,181 billion cfu/day
Margin of Safety	Implicit
Required Percent Reduction	73 %

Public Participation

The public and stakeholder participation process in TMDL development, "Public Participation in TMDL Projects: A Guide for Lead Organizations," is available on the Web at <www.state.tx.us/implementation/water/tmdl/tmdlresources.html>.

In accordance with requirements of Texas House Bill 2912, an official steering committee of stakeholders was established for the Upper Oyster Creek TMDL project in 2002. The first steering committee meeting was held in June 2003, and one or two meetings have been held each year since that time at facilities in Sugar Land. The steering committee members represent a broad array of interests in the watershed, such as local industries (including wastewater treatment facilities), landowners, environmental

groups, and local and regional government groups. The stakeholder committee has had very little turnover over the life of the project. Their knowledge of the watershed and consistency in attending meetings and providing input have been—and will continue to be—a valuable resource for restoring the beneficial uses of Upper Oyster Creek.

Implementation and Reasonable Assurances

The TMDL development process involves the preparation of two documents:

- 1) a TMDL, which determines the maximum amount of pollutant a water body can receive in a single day and still meet applicable water quality standards, and
- 2) an implementation plan (I-Plan), which is a detailed description and schedule of the regulatory and voluntary management measures necessary to achieve the pollutant reductions identified in the TMDL.

The TCEQ is committed to developing I-Plans for all TMDLs adopted by the commission and to ensuring the plans are implemented. I-Plans are critical to ensure water quality standards are restored and maintained. They are not subject to EPA approval.

The TCEQ works with stakeholders to develop the strategies summarized in the I-Plan. I-Plans may use an adaptive management approach that achieves initial loading allocations from a subset of the source categories. Adaptive management allows for development or refinement of methods to achieve the environmental goal of the plan.

Periodic and repeated evaluations of the effectiveness of implementation methods assure that progress is occurring, and may show that the original distribution of loading among sources should be modified to increase efficiency. This adaptive approach provides reasonable assurance that the necessary regulatory and voluntary activities to achieve the pollutant reductions will be implemented.

Implementation Processes to Address the TMDL

Together, a TMDL and a TMDL I-Plan direct the correction of unacceptable water quality conditions that exist in an impaired surface water in the state. A TMDL broadly identifies the pollutant load goal after assessment of existing conditions and the impact on those conditions from probable or known sources. A TMDL identifies a total loading from the combination of point sources and nonpoint sources that would allow attainment of the established water quality standard.

A TMDL I-Plan specifically identifies required or voluntary implementation actions that will be taken to achieve the pollutant loading goals of the TMDL. Regulatory actions identified in the I-Plan could include adjustment of an effluent limitation in a wastewater permit, a schedule for the elimination of a certain pollutant source, identification of any nonpoint source discharge that would be regulated as a point source, a limitation or prohibition for authorizing a point source under a general permit, or a required modification to a storm water management program (SWMP) and pollution prevention plan (PPP). Strategies to optimize compliance and oversight are identified in an I-Plan when necessary. Such strategies may include additional monitoring and reporting of

effluent discharge quality to evaluate and verify loading trends, adjustment of an inspection frequency or a response protocol to public complaints, and escalation of an enforcement remedy to require corrective action of a regulated entity contributing to an impairment.

A TMDL and the underlying assumptions, model scenarios, and assessment results are not and should not be interpreted as required effluent limitations, pollutant load reductions that will be applied to specific permits, or any other regulatory action necessary to achieve attainment of the water quality standard. In simple terms, a TMDL is like a budget that determines the amount of a particular pollutant that the water body can receive and still meet a water quality standard. The I-Plan adopted by the Commission will direct implementation requirements applicable to certain sources contributing a pollutant load to the impaired water.

The I-Plan will be developed through effective coordination with stakeholders affected by or interested in the goals of the TMDL. In determining which sources need to accomplish what reductions, the I-Plan may consider factors such as cost, feasibility, the current availability or likelihood of funding, existing or planned pollutant reduction initiatives such as watershed-based protection plans, whether a source is subject to an existing regulation, the willingness and commitment of a regulated or unregulated source, and a host of additional factors. Ultimately, the I-Plan will identify the commitments and requirements to be implemented through specific permit actions and other means. For these reasons, the I-Plan that is adopted may not approximate the predicted loadings identified category by category in the TMDL and its underlying assessment, but with certain exceptions, the I-Plan must nonetheless meet the overall loading goal established by the Commission-adopted and EPA-approved TMDL.

An exception would include an I-Plan that identifies a phased implementation that takes advantage of an adaptive management approach. It is not practical or feasible to approach all TMDL implementation as a one-time, short-term restoration effort. This is particularly true when a challenging wasteload reduction or load reduction was required by the TMDL, high uncertainty with the TMDL analysis exists, there is a need to reconsider or revise the established water quality standard, or the pollutant load reduction would require costly infrastructure and capital improvements. Instead, activities contained in the first phase of implementation may be the full scope of the initial I-Plan and include strategies to make substantial progress towards source reduction and elimination, refine the TMDL analysis, conduct site-specific analyses of the appropriateness of an existing use, and monitor in stream water quality to gauge the results of the first phase. Ultimately, the accomplishments of the first phase would lead to development of a phase two or final I-Plan or revision of TMDL. This adaptive management approach is consistent with established guidance from EPA (See August 2, 2006, memorandum from EPA relating to clarifications on TMDL revisions).

The TCEQ maintains an overall water quality management plan (WQMP) that directs the efforts to address water quality problems and restore water quality uses throughout Texas. The WQMP is continually updated with new, more specifically focused WQMPs, or "water quality management plan elements" as identified in federal regulations (40

Code of Federal Regulations (CFR) Sec. 130.6(c)). Consistent with federal requirements, each TMDL is a plan element of a WQMP and Commission adoption of a TMDL is state certification of the WQMP update.

Because the TMDL does not reflect or direct specific implementation by any one pollutant discharger, the TCEQ certifies additional "water quality management plan elements" to the WQMP once the I-Plan is adopted by the Commission. Based upon the TMDL and I-Plan, the TCEQ will propose and certify WQMP updates to establish required water-quality-based effluent limitations necessary for specific TPDES wastewater discharge permits. The TCEQ would normally establish best management practices (BMPs), which are a substitute for effluent limitations in TPDES MS4 storm water permits as allowed by the federal rules where numeric effluent limitations are infeasible (See November 22, 2002, memorandum from EPA relating to establishing TMDL WLAs for storm water sources). Thus, TCEQ would not identify specific implementation requirements applicable to a specific TPDES storm water permit through an effluent limitation update. However, the TCEQ would revise a storm water permit, require a revised SWMP or PPP, or implement other specific revisions affecting storm water dischargers in accordance with an adopted I-Plan.
