BACKGROUND

The Texas Commission on Environmental Quality (TCEQ) works with local planning districts, the Texas Department of Transportation (TxDOT), and the Texas Transportation Institute (TTI) to provide on-road mobile source emissions inventories of air quality pollutants. TxDOT typically funds the transportation conformity determinations required under 40 CFR Part 93. TCEQ funds mobile source inventory work in support of the federal Clean Air Act Amendment (CAAA) requirements, such as attainment of the National Ambient Air Quality Standards (NAAQS, 42 USCA 7409), and the study and control of hazardous air pollutants (HAPs), including those from motor vehicles and/or motor vehicle fuels (as mandated under CAAA sections 202 and 211).

TCEQ emissions inventory development activities include inventory development, methodology updates, data gathering, analysis and assessment, and planning for future requirements. In addition to meeting the basic inventory development requirements, Texas has consistently used state-of-the-art methodologies and up-to-date data sets to develop highly detailed, completely defensible on-road mobile State Implementation Plan (SIP) inventories. This level of commitment requires the constant monitoring and update of emissions inventory and control strategy reduction estimation procedures to include the latest methods and data.

TCEQ is continuing its progress toward meeting the requirements of the U.S. Environmental Protection Agency's (EPA) eight-hour ozone standard. As part of the on-going eight-hour attainment SIP planning and development process, new or supplemental data sources are periodically identified and assessed. The assessment and incorporation of the TranStar data into the emissions inventory development process is such an opportunity. Created in 1993 and officially opened in April 1996, TranStar is a consortium partnership formed by the transportation and emergency management agencies in the greater Houston region. The partnership is responsible for coordinating the planning, design, and operations of transportation systems and emergency management functions and coordinates the development and deployment of Intelligent Transportation Systems (ITS). Emergency management personnel housed at Houston TranStar monitor potential emergencies and disasters with state-of-the-art technology and other hi-tech systems such as Flood Warning Monitors, Doppler Radar, Satellite Imagery, and Weather Data directly from the National Weather Service.

TASK 2: LINK SPEED ESTIMATION IMPROVEMENTS FOR MOBILE6 MODELING USING TRANSTAR DATA

Task 2 Description

The accuracy of oxides of nitrogen (NO_x) and volatile organic compound (VOC) emissions estimates are critical in SIP modeling and control strategy development. This project is part of ongoing efforts to ensure that accurate and detailed mobile source emissions inventories are developed on a schedule to assure availability of all inventories required to support SIP development and TCEQ planning activities.

Development of on-road mobile source emissions inventories for major metropolitan areas is typically based on travel demand models (TDM) that estimate vehicle miles traveled (VMT) for thousands of roadway “links” in the travel network. An additional step in this process is the estimation of average hourly operating speeds for each of these links. This recursive estimation of link speed is a central part of the emissions estimation process, since speed is a critical parameter in emissions estimation, and TDMs are typically calibrated on link volume (as opposed to link speed). Current practice relies on the application of a speed model for these link speed estimates. These speed models are applied using local inputs, but are based on a well-established standard generalized structure, which relates volume and capacity to speed.

There are two types of TranStar historical data. Both contain segment and date/time identification information. One contains segment distance and travel time to produce speed, the other estimates speed directly and includes volume. The former is suitable for historical comparisons of observed values. The latter is suitable for speed model validation and calibration. Both are put through TranStar’s own quality assurance (QA) process. For this task, TTI accomplished the following activities:

1. obtained historical TranStar data, with particular emphasis on the episode periods of interest noted below;
2. obtained or calculated the estimated average hourly operating speeds for each identifiable TranStar segment, by day of week;
3. ensured internal consistency in the available historical data, either directly or through confirmation of TranStar’s QA process. TTI analyzed and compared average hourly operating speeds for internal consistency, including identifying any significant outliers (extreme values) from mean or typical hourly operating speed;
4. analyzed and compared average hourly operating speeds for consistency with similar speeds generated by the current link speed estimation procedure, including an overall comparison of average hourly speeds between the TranStar segments and the TDM links;
5. identified any patterns that emerged in the data relating to hourly differences between the TranStar and TDM data sets; and
6. used the portion of the TranStar data set that contained traffic volume information, estimated the speed model parameters implied by TranStar data, and compared these with current TDM speed model parameters and recommend revisions as appropriate.

In addition, TTI provided QA oversight and review of all data sets (using appropriate statistical analysis software). Both the analytical approach and results are fully documented in the report submitted to TCEQ.

Task Deliverables

Interim deliverables are an informal Technical Note (a narrative in memorandum format that explains the task, the approaches used, and the findings) provided to the Project Manager in the

specified format, which is supported by electronic document files. All pertinent data are being submitted in the specified electronic format. (No FORTRAN source code or executable files were developed under this task.) CD-ROM is used to record the final data and supporting documentation. TTI is providing five copies of both the review draft and the final report. One of the copies is an unbound original suitable for copying. Electronic copies of all materials related to the task report, to document results and conclusions (e.g., data, work files, text files, etc.), or developed as work products under this contract were provided as requested by TCEQ.

Acknowledgments

Dennis Perkinson, Ph.D., performed the statistical analyses used in this study. L.D. White, of TTI, provided preprocessing and screening of the data assembled for this study. Darrell Borchardt, of TTI's Houston office, was instrumental in providing access to TranStar data. Gary Lobaugh, of TTI, was responsible for editing, design, and production of this Technical Note. Dr. Perkinson was the principle investigator for this project. This work was performed by TTI under contract to TCEQ. Christopher Kite was the TCEQ project technical manager.

INTRODUCTION

Houston TranStar gathers various "real time" vehicle travel information and reports average operating speeds for various highway segments throughout the metropolitan area. The Houston TranStar consortium is a partnership of four local government agencies responsible for transportation management. These agencies are:

- TxDOT;
- Harris County;
- Metropolitan Transit Authority of Harris County (METRO); and
- City of Houston.

This project analyzed TranStar data for incorporation into the current link speed estimation procedure. The results of this analysis will improve emissions estimates for photochemical modeling applications. TTI obtained all available TranStar historical data for 2005 and 2006. TCEQ previously identified specific time periods of special interest because they are ozone exceedance episodes currently under review by the TCEQ. These are:

- May 19 – June 3, 2005;
- June 17 – June 30, 2005;
- July 26 – August 8, 2005;
- May 31 – June 16, 2006; and
- August 1 – October 15, 2006 (i.e., period of TxAQS II Study).

These data were assessed for incorporation into the current link speed estimation procedure. Specifically, observed speeds are compared by episode for each corridor and day type using the Automated Vehicle Identification (AVI) TranStar data. Current speed model results are compared to the observed speeds using the TranStar Wavetronix data, differences noted, and any indicated modification to current speed model parameters provided.

AVI DATA VERSUS WAVETRONIX DATA

As noted previously, there are two types of TranStar historical data. Both contain segment and date/time identification information. One is AVI system data and contains segment distance and travel time to produce speed. These data are suitable for historical comparisons of observed values. The other TranStar data are radar based (using proprietary Wavetronix technology, hence referred to hereafter as Wavetronix data) and include volume as well as speed. By virtue of the volume data, the Wavetronix data are suitable for speed model validation and calibration. Both were processed through separate TranStar QA processes. The geographic scope of the Wavetronix data is more limited than the AVI data.

AVI Data - Episode Comparisons

TranStar AVI data is based on vehicles equipped with transponder tags, functioning as virtual probes. In the TranStar application, the transponders are “EZ Tag” automatic toll collection system transponders provided by the Harris County Toll Road Authority. Transponder tag readers are located at intervals along selected freeways (typically 1-to-5 miles). Time and location is noted as each transponder-equipped vehicle passes a tag reader. This information is then used to calculate the speed between tag readers, aggregated across vehicles and time to produce an estimate of the speed for that link during the specific time period.

TranStar AVI speed data were assembled for 2005 and 2006, encompassing all the episode periods of interest specified by TCEQ. A non-episode residual period was also defined and included in the analysis. (See Table 1.) The application of TranStar’s own internal QA protocol was confirmed. The 2006 data contain January through November data. Typically, only 10 days or so of December are used by TranStar to avoid recording atypical higher speeds during holiday periods. December data are not used at all starting in 2006. The individual roadway segments included in the AVI data are listed in the appendix.

Occasionally extreme speed values result from various types of tag reader error (e.g., time-of-day calibration, synchronization with the server at TranStar, etc.). These are of limited duration, but can produce extreme values for a period, given the sampling regime. TranStar has algorithms that prevent these extreme values from being posted on the website in real time. Year-end manual review of the data is also performed.

To correct for extremely high speeds, all calculated speeds greater than 80 mph are deleted. Errors on the slow side are more complicated and cannot be eliminated by a speed threshold since valid extremely slow speeds do exist, typically during incidents. However, extremely low speeds are easier to catch during the manual year end review, so those attributable to error (e.g., faulty equipment) as opposed to those actually occurring (e.g., attributable to incidents) are removed during the manual review process.

In addition, TTI reviewed the entire data set for extreme values and other anomalies specifically for this analysis. From this review, three corridors and several segments were dropped from the analysis. Two corridors (SH 146 and Spur 330) are recent additions and were not operational during a substantial portion of the episode period of interest. The third corridor (I-10 Katy) experienced data reliability problems due to construction during the period of interest. An additional few segments in the remaining corridors were dropped due to missing

data or obvious instability in the data (typically due to hardware/tag reader failure). While the loss of any data is regrettable, the remaining data set is extremely large and provides a sound basis for extensive comparisons (N > 10,000,000 observations on 218 roadway segments in 15 corridors, see Table 2 and Figure 1).

Speed profile comparisons were developed for hourly average speed for each episode and a separate non-episode category, by day of week. Plots of these comparisons are provided in Appendix B, along with tables of the values (Appendix C). Segment specific tables including minimum and maximum values, as well as the average speed, are provided electronically, as are the data sets themselves.

Table 1. AVI Episode Comparison Key

Episode Designation	Episode Description
A	May 19 – June 3, 2005

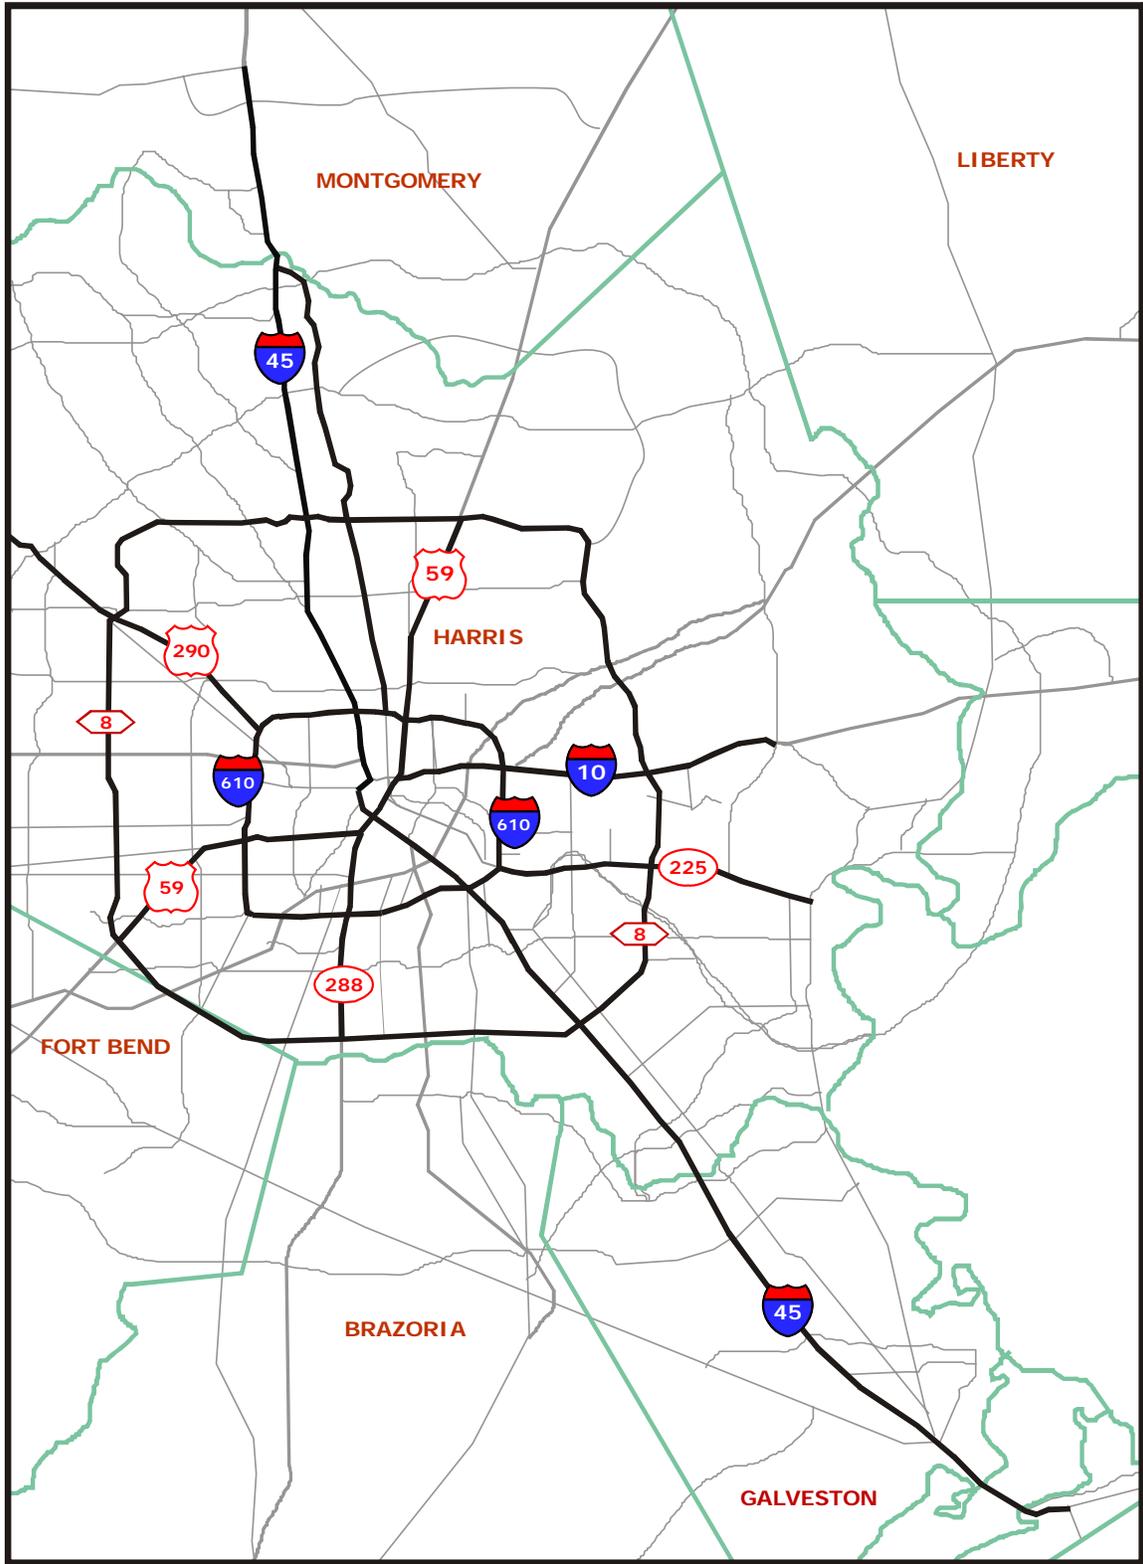

Figure 1. AVI Data Collection Area

Wavetronix Data - Speed Model Verification

Congested speed is a critical parameter for estimating emissions. Similarly, capacity, freeflow speed, and traffic volume are critical parameters for determining speed. Capacity is the maximum flow past a given point on a roadway and varies by the type of roadway (i.e., by functional classification). Freeflow speed is the maximum speed that traffic will move along a given roadway if there are no impediments (i.e., congestion).

TranStar speed and volume data are collected using a proprietary radar based vehicle detection technology (Wavetronix). Unlike the AVI technology, no on-board hardware is required and all vehicles are monitored. This allows the collection of both volume and speed. This technology was deployed in four corridors during the period of interest for this analysis (see Table 3).

TranStar Wavetronix speed and volume data were assembled for 2005 and 2006, encompassing all the episode periods of interest specified by TCEQ. These data are not separated by episode period or location, however, since the interest in this portion of the analysis is with the volume/speed relationship, which is by definition not location or calendar specific. It is, of course, capacity specific. Therefore, lanes and roadway type are critical parameters, along with area type, which is also related to capacity, but indirectly. These parameters were noted for the Wavetronix collection segments and locations. The application of TranStar's own internal QA protocol was confirmed.

In addition, TTI reviewed the entire data set for extreme values and other anomalies specifically for this analysis. From this review, two segments were dropped from the analysis, due to missing or widely variant data values. In addition, the most extreme low values and the most extreme high values were dropped. The actual number of observations actually deleted varies with the speed model being analyzed, but constitute less than 5 percent of the observations in all cases. The loss of any data is regrettable, but the remaining data set provides an ample basis for the analysis of the observed speed/volume relationship ($N > 162,200$ observations in all cases, see Table 3 and Figure 2).

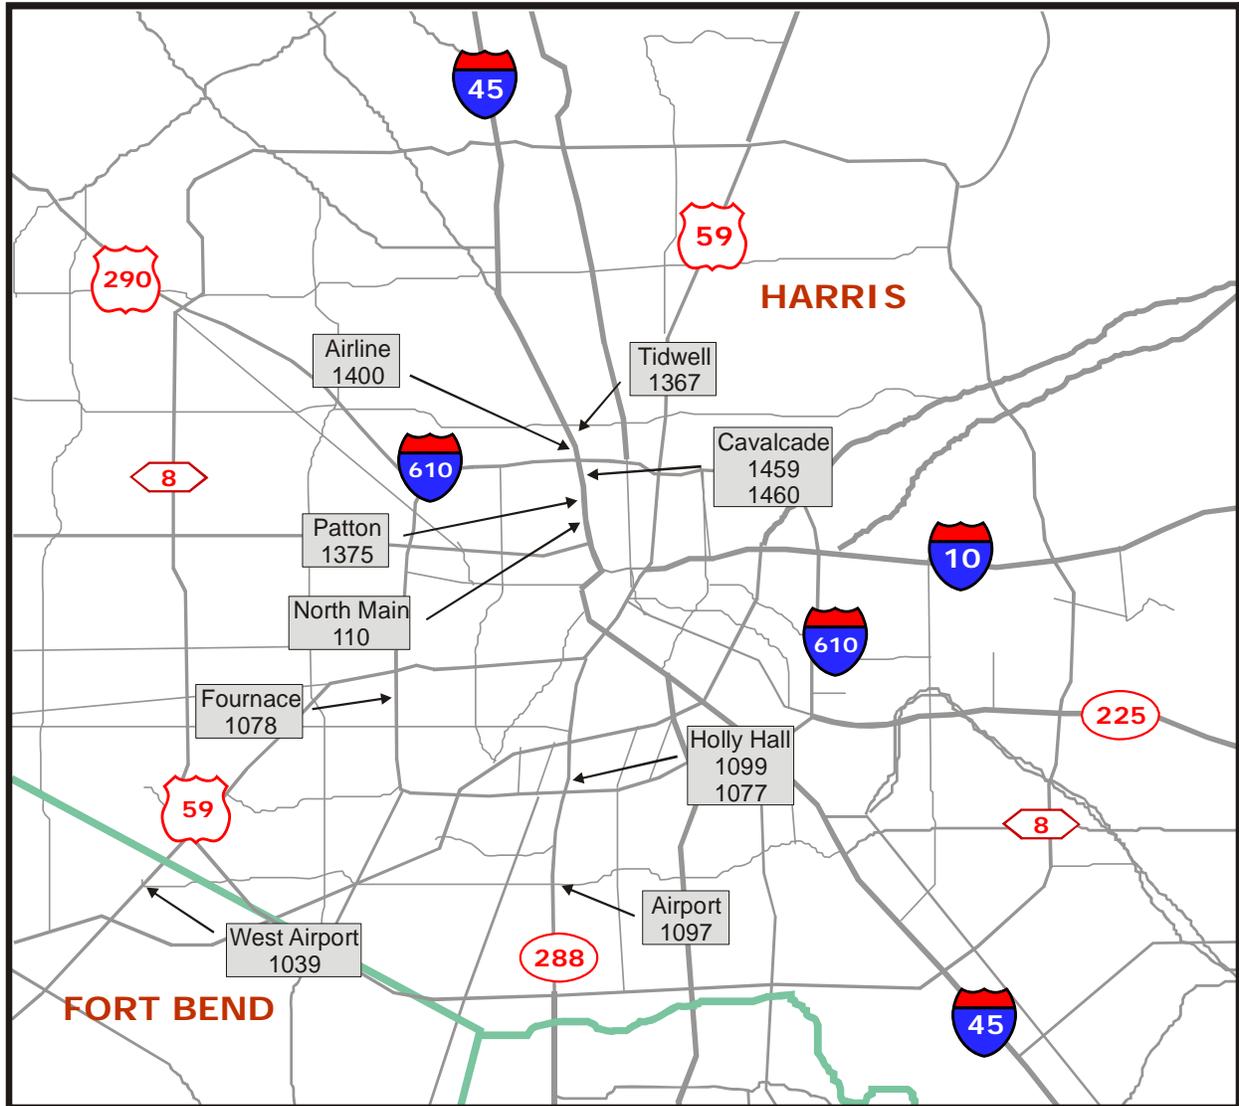

Figure 2. Wavetronix Data Collection Stations

TTI SPEED MODEL

The TTI speed model calculates delay on the link and then applies this delay to the freeflow speed to estimate the operational speed on the link. The volume/delay relationship is:

$$\text{Delay} = \text{Min} \left[A e^{B \left(\frac{V}{C} \right)}, M \right]$$

Where:

- Delay = congestion delay (in minutes/mile);
- A & B = volume/delay equation coefficients;
- M = maximum minutes of delay per mile; and
- V/C = time-of-day directional volume-to-capacity (v/c) ratio.

Delay model parameters A, B, and M vary by facility category (high-capacity versus low-capacity). Given the delay (in minutes/mile) and the estimated freeflow speed, the directional congested speed is calculated by time period and direction for each link as follows:

$$\text{Congested Speed} = \frac{60}{\frac{60}{\text{Freeflow Speed}} + \text{Delay}}$$

Speed estimates were developed using the standard TTI speed model applied to the observed Wavetronix data volumes, for the observed roadway types and lane configurations. These estimated values were then compared to the observed values from the Wavetronix data at several levels of aggregation. Note that in terms of the parameters of the TTI speed model, all the Wavetronix data collection stations are on the same roadway category (Interstate/Freeway) and in the same area type (Urban).

At the most general and representative level, there is virtually no difference in the speed predicted by the TTI speed model and the observed speed. The aggregate difference between estimated and observed speed is less than 0.02 mph (i.e., Mean Estimated - Mean Observed = 0.017 mph, see Table 4). While variance naturally increases as the level of aggregation is reduced, the comparison at the corridor level is similarly strong. The interpretation of these statistics is that overall, an estimate of link speed using the current speed model will be within 0.02 mph of the observed speed. Technically this conclusion is limited to Interstate/Freeway road classifications in Urban areas (as defined by the Highway Performance Monitoring System [HPMS]). The corridor level comparisons can be interpreted as indicating the degree of variance in estimated versus observed speed at the next level of disaggregation. A segment level summary comparison is provided in Appendix D.

**Table 4. TTI Speed Model
Mean Estimated versus Observed Speed by Corridor**

Corridor	Obs (N)	Mean Difference
I-45	42,191	0.702
I-610	29,851	2.860
SH-288	54,550	-1.745
US-59	40,667	-0.415
All	167,259	0.017

HOUSTON SPEED MODEL

The Houston speed model calculates operational link speeds using the travel model speed, speed factors (consisting of a freeflow speed factor and level-of-service [LOS] E speed factor) and a v/c ratio based speed reduction factor (SRF) for each link. The SRFs are unique to each travel demand model and are recalculated for each model.

The speed factors are used to convert the travel model speed to a freeflow speed and an LOS E speed (i.e., application of these factors results in two speeds). These factors are grouped into seven functional groups. For each link, the SRF is determined using the v/c ratio, the area type, and the roadway functional classification. The SRFs are for v/c ratios of 0 to 1 in 0.05 increments. For v/c ratios greater than 1.0, a SRF is not used. The speed model for v/c ratios from 0.00 to 1.00 is:

$$S_{v/c} = S_{0.0} - SRF_{v/c} \times (S_{0.0} - S_{1.0})$$

Where:

- $S_{v/c}$ = estimated directional speed for the forecast v/c ratio on the link;
- $S_{0.0}$ = estimated freeflow speed for v/c ratio equal to 0.0;
- $S_{1.0}$ = estimated LOS E speed for v/c ratio equal to 1.0; and
- $SRF_{v/c}$ = speed reduction factor for given v/c ratio ($0.0 \leq v/c \leq 1.0$).

For v/c ratios greater than 1.0, no SRF is used and the upper limit is imposed on the v/c ratio. The resulting speed model configuration is:

$$S_{v/c} = S_{1.0} \times (1.15 / (1.0 + (0.15 \times (v/c)^4)))$$

Where:

- $S_{v/c}$ = estimated directional speed for the forecast v/c ratio on the link;
- $S_{1.0}$ = estimated LOS E speed for the v/c ratio equal to 1.0; and
- v/c = the forecast v/c ratio on the link. (If $v/c \geq 1.5$ then $v/c = 1.5$.)

Due to the complex and interrelated structure of the Houston speed model, some slight modification of the application was necessary for this analysis. Specifically, TDM-based link speeds were set independently of the travel demand model. This was necessary to focus the analysis on both the accuracy of the Houston speed model itself and its ability to replicate observed speeds, rather than the travel models' structure and calibration. In addition, the protocol for the application of the SRF was modified slightly by using 0.05 incremental categories of v/c ratio applied to the 0.05 categories of SRF, rather than interpolating the SRF value to match the v/c ratio. The difference is computational and the change in the resulting speed estimate is trivial.

Speed estimates were developed using the latest available applied version of the Houston speed model applied to the observed Wavetronix data volumes, for the observed roadway types and lane configurations. These estimated values were then compared to the observed values from the Wavetronix data at several levels of aggregation. Note that in terms of the Houston speed model parameters, all the Wavetronix data collection stations are on the same roadway category (Interstate/Freeway) and in either Urban or Urban Fringe area types.

Once again, at the most general and representative level, there is virtually no difference in the speed predicted by the Houston speed model and the observed speed. The aggregate difference between estimated and observed speed is less than 0.06 mph (i.e., Mean Estimated - Mean Observed = 0.056 mph, see Table 5). While variance naturally increases as the level of aggregation is reduced, the comparison at the corridor level is similarly strong. The interpretation of these statistics is that overall, an estimate of link speed using the current speed model will be within 0.06 mph of the observed. Technically this conclusion is limited to Interstate/Freeway road classifications in Urban and Urban Fringe areas (as defined by the Houston-Galveston Area Council [H-GAC] for their travel demand modeling). The corridor level comparisons can be interpreted as indicating the degree of variance in estimated versus observed speed at the next level of disaggregation. A segment level summary comparison is provided as an appendix.
