Regulated Entity Number: RN100223130
Customer Reference Number: CN600126973

Dear Senator Perry:

This letter notifies you that the Texas Commission on Environmental Quality has received a federal operating permit (FOP) initial issuance application for a site located in your district. This application is being processed in an expedited manner, as allowed by the commission's rules in 30 Texas Administrative Code, Chapter 101, Subchapter J. As part of this permitting process, the applicant is required to publish a formal newspaper public notice. The notice will inform the public of their right to make comments or request a public hearing. This link to an electronic map of the site or facility's general location is provided as a public courtesy and not part of the application or notice. For exact location, refer to application. <https://gisweb.tceq.texas.gov/LocationMapper/?marker=-101.831111,33.566388&level=13>.

The FOP program regulates both new and existing major sources of emissions. The goal of the program is to improve air quality in Texas through increased compliance by codifying existing applicable regulatory requirements into the FOP. The FOP provides the applicant authorization to operate the equipment at the site. The FOP identifies and codifies air emission requirements (known as applicable requirements) that apply to the emission units at the site. The FOP does not authorize construction of emission units or emissions from those units. The New Source Review (NSR) permit is the mechanism for these authorizations.

3. PROCESS DESCRIPTION

The Avenue A Facility is a cottonseed processing plant. The primary products produced from the raw cottonseeds are lint, hulls, meal, and vegetable oil. In the processing cycle, short-cut lint is first removed from the gray seeds in a delinting process. The delinted cotton seeds are then hulled to remove the outer seed hulls from the inner seed meats. The process of extracting the vegetable oil from the seed meats consists of an initial seed preparation and conditioning, then oil extraction, solvent/oil separation, desolventization and treatment of desolventized flakes, and finally oil refining. A more detailed description of these processes is included in the following sections.

3.1 Seed Receiving and Storage

The Avenue A Facility receives cottonseed by truck. Each truck is weighed by on-site scales before being sent to one of eight seed dumps. The trucks are unloaded at the seed dumps by elevating the trucks to a 45-degree angle. The seed is released from the rear of the truck and is dumped into a seed hopper. Seed collected in the seed dump hoppers is transported by screw conveyor to bucket elevators that direct the seed to one of numerous conveyors leading to the seed storage houses or open storage piles. Mechanical conveying is used to transfer seed at this point in the process since pneumatic conveying could result in seed damage. The elevator and conveyors are covered to shelter the seed from adverse meteorological conditions and to specifically reduce potential fugitive wind-blown emissions.

Each seed house and open seed storage pile has an associated cooling system. The purpose of the cooling system is to maintain the air temperature inside the seed pile to below 100°F in order to prevent seed deterioration and spontaneous combustion. Each cooling system is equipped with fans located outside the storage unit which pull ambient air down through the seed piles to maintain cool temperatures. The fans generally operate from late fall into spring when the ambient air is cool and relatively dry. Cooling fans are not used during the summer months when ambient temperatures are high since this would only serve to heat the interior of the piles.

As needed, seeds from the open piles and houses are conveyed back to either seed dump #1 or the cleaning room dump. Both dumps feed directly into the gray seed storage tanks, the initial point of entry into the production process.

3.2 Seed Cleaning

Once ready for processing, the cottonseed is mechanically conveyed from the Gray Seed Tanks into the Cleaning Room. The seed is then processed through the seed cleaners (controlled by the proposed Filters 1, 2, 3, and 4). The seed cleaners separate trash larger than seed size and smaller than seed size by a series of screens. By using air and gravity, rocks, nuts, twigs, and other materials that are the size of the seed also drop out. The cleaned gray seed is mechanically conveyed to the proposed Clean Seed Tanks (Tanks 4 and 5). Dirt and debris is collected and loaded outside the Cleaning Room into garbage trucks for disposal off-site.

3.3 Delinting and Lint Cleaning

From the Clean Seed Tanks, the cleaned cottonseed is mechanically conveyed to the first-cut delinters in the Lint Room. These units consist of several saws that act to remove the longest lint from the seed. During the process of removing lint from seed, some seed parts and foreign material remain caught in the lint. The

first-cut lint beaters are used to clean the lint. These machines are used to beat, stir and convey the lint over perforated metal which is sized to remove the various sizes of foreign material. The exhaust streams from the Lint Room are proposed to be controlled by drum filters for secondary particulate emission control (Filters 5, 6, 7, and 8). The material removed from the lint by the beaters consists of hulls and meats and is recycled to the Huller room.

The partially delinted seed is next processed through the second-cut delinters. These delinters are similar in appearance and operation to the first-cut delinters. Similar to the first-cut delinters, some seed parts and foreign matter remain caught in the lint. The second-cut lint beaters are used to clean the lint. The material removed from the lint by the beaters consists of fine hulls and meats and is also recycled to the Huller room. After the seed is delinted in the Lint Room, it is conveyed either to one of four Black Seed Storage Tanks at the Huller Room, or when these tanks are full, to the Surge Black Seed Tanks near the Bale Press Area.

The clean first-cut and second-cut lint is then pneumatically conveyed through tipping from the proposed Black Seed Tanks (Tanks 6, 7, 8, and 9) to the Bale Press Area for baling into lint bales. The first-cut lint consists of long cotton fibers while the second-cut lint consists of much shorter cotton fibers. Inside the Bale Press Area building, a floor sweep is used to remove excess lint that collects on the floor as the lint is handled and baled. The excess lint is pneumatically conveyed back to the Bale Press Area. Finished bales of lint are sent to covered storage. Baled lint is loaded into trucks or into boxcars for shipment.

The exhaust streams from the Bale Press Area are proposed to be controlled by drum filters for secondary particulate emission control (Filters 9 and 10).

3.4 Hulling and Separating

Seeds are conveyed from the Black Seed Tanks into the Huller Room for processing. In the Huller Room, the seeds pass first through hullers that cut the seeds open to release the meats. The meats are separated from the hulls and are collected in a meats bin. The meats are then conveyed to a cooker system in the extraction preparation area. Any remaining uncut seeds are mechanically conveyed back to the hullers until cut.

Hulls and light meats particles from the hullers are pneumatically conveyed to the hull beaters for additional processing and separating. Here, fine meats are beaten out and directed to the meats stream. The hulls then pass through a tailing and finish beater for final meats separation. The hulls are separated and mechanically conveyed to the Hull Loading House. All emission from cyclones used in the Huller Room for pneumatic transfer of materials are routed to one of three secondary filtration systems consisting of two drum filters (HR01 and HR02) and a baghouse (HR03).

During distribution and loadout, the hulls are proposed to be controlled by a drum filter (Filter 13) and released from a covered conveyor into the top of a truck in the Hull Loading House, an open-ended building. Additionally, hulls can be stored on the north side of the plant in the Excess Hull Storage House. Near this house, hulls can be loaded into rail cars for shipment. However, the majority of hulls produced at the Avenue A Facility are shipped by truck.

3.5 Oil Extraction

Before being directed to the oil extraction unit, the seed meats are processed in a cooker system. In the cooker system, the meats are steam-heated. With the added moisture the seeds are "flaked" in a series of

flaking rolls. Flaking is necessary to improve oil extraction. The flakes are then processed in an expander room. Steam is injected into a vessel with the flakes at high pressure. As the steam-pressurized flakes are forced through a set of expanders, the drop in pressure causes the steam to be rapidly released from the flakes. This action creates "collets," which are porous flakes of seed meat.

Solvent extraction is the most efficient method of recovering oil from most oil-bearing vegetable seeds. Extraction is accomplished through a counter-current procedure in which contact between the oil-bearing seed and solvent is achieved. The Avenue A Facility retains the ability use either an n-hexane solvent or an iso-hexane solvent, as operations dictate.

With the extraction unit, cottonseed flakes are continuously processed inside a round vessel with 20 individual extraction cells. Hexane enters the extractor basket near the discharge hopper and flows through the bed of flakes. The oil flows countercurrently through the flakes through four stages. The percentage of oil in the miscella increases with each stage such that at the final stage, a full miscella is withdrawn consisting of approximately 30% oil and 70% hexane. To ensure uniform distribution of the solvent application and drainage to the 20 cells, the width and depth of the extractor is fixed, but the speed at which it rotates may be varied in order to obtain the desired capacity. The bed of flakes remaining after the final wash of pure hexane is drained dry. The bottom of the extractor then opens and the spent flakes drop out and are conveyed to the desolventizer/toaster for desolventizing.

The extractor temperature is maintained between 135 and 140°F by adjusting the temperature of the incoming collets appropriately. Temperature is also maintained by automatic control of the fresh hexane temperature with a hexane heater. If the temperature in the extractor rises above 150°F (an upset condition), the hexane begins to flash and pressurizes the vent system. If the pressure reaches 3 1/2 inches of water column, a pressure relief valve on the extractor will open to relieve the pressure.

After extraction, the solvent and the oil (miscella) is separated by distillation. From the extractor collecting rings, miscella containing oil, solvent, and suspended solids is filtered through a strainer on a continuous basis before refining. The amount of suspended solids that is captured during filtration depends on the quality of the oil seed being processed. After filtration, the miscella is heated in an evaporator. Approximately 90 to 95 percent of the solvent will be evaporated in the evaporator where it is condensed and reclaimed. Oil effluent from the evaporator then passes to a vacuum distillation column where most of the remaining 5 to 10 percent of the solvent is steam-stripped from the oil. Overhead vapor containing residual solvent is condensed, collected, and decanted along with the solvent condensed from the evaporators. Finally, the solvent is mixed with fresh make-up solvent and recycled through the extraction system.

Oil separated from the solvent is refined with caustic. The oil is preheated and mixed with lye in a series of vertical mixers. In the mixers, solids are agglomerated while in suspension. These solids are colorbodies, glycerides and fatty acids (soaps). The agglomerated solids are then separated from the refined oil. The soaps, which contain approximately 5-7% hexane, are pumped to the desolventizer with the spent meal. The soaps stay in the dried meal as fat. The refined oil is then processed through a second stage evaporator. The refined oil generated from this process is termed PBSY oil.

3.6 Oil Processing

PBSY oil is stored in one of numerous oil storage tanks on-site. The oil is eventually sent to the vegetable oil bleaching and deodorizing plant for further processing and refining. The entire process of bleaching and

deodorizing the cottonseed oil is conducted through an enclosed system of pumps, piping, and vessels and there are no hydrocarbons involved in the process.

In the bleaching operation, color bodies and other impurities are removed from the crude oil. The operation consists of adding bleaching clay, allowing it to absorb the color bodies before the clay is removed by filtration. As the oil leaves the filters, nitrogen is injected to enhance bleached oil stability. The clay filter cake goes to disposal.

Deodorization is the final processing step to produce an edible vegetable oil. It is a process of steam stripping volatile, unfavorable, odoriferous, and flavored substances from the relatively non-volatile oil to produce a bland and tasteless product. The process consists of deaeration and heating of the oil to elevated temperatures and then subjecting the oil to low absolute pressure and sparging steam. After deodorizing, nitrogen is again added to the oil to enhance its storage stability.

The refined vegetable oil is stored in nitrogen blanketed tanks prior to sale. Finish oil shipments are pumped to tank cars or truck loadout stations with nitrogen blanketing.

3.7 Solvent/Meal Separation

The oil seed flakes that are processed through the extractor become saturated with solvent. In order to reclaim the solvent and make the meal edible for animals, the flakes are fed to a desolventizer toaster (DT). This device is similar to a stack cooker in which steam is used to vaporize and strip out occluded solvent from the meal. In addition to vaporizing most of the solvent, the steam also adds to the moisture content of the meal thus minimizing fugitive dust emissions as the meal is conveyed to the meal dryer/cooling system. Solvent stripped from the meal is fed to the main evaporator. The meal is cooled in a meal dryer/cooler and is mechanically conveyed to the meal processing area.

3.8 Meal Processing and Loadout

Meal is stored in one of several meal storage bins or to the Meal Storage House. Bulk meal that is ready to be loaded out is ground, and then proposed to be controlled by drum filters (Filters 11 and 12). Ground meal is mechanically conveyed into hoppers that drop the meal into trucks inside the Primary Meal Processing building. When the Primary Meal Loadout Station is down, bulk meal can also be transferred mechanically to the Secondary Meal Loadout Station for drop loading into trucks.

4. PM AND CAM REQUIREMENTS

This section of the application addresses monitoring requirements associated with Periodic Monitoring (PM) and Compliance Assurance Monitoring (CAM).

4.1 Periodic Monitoring

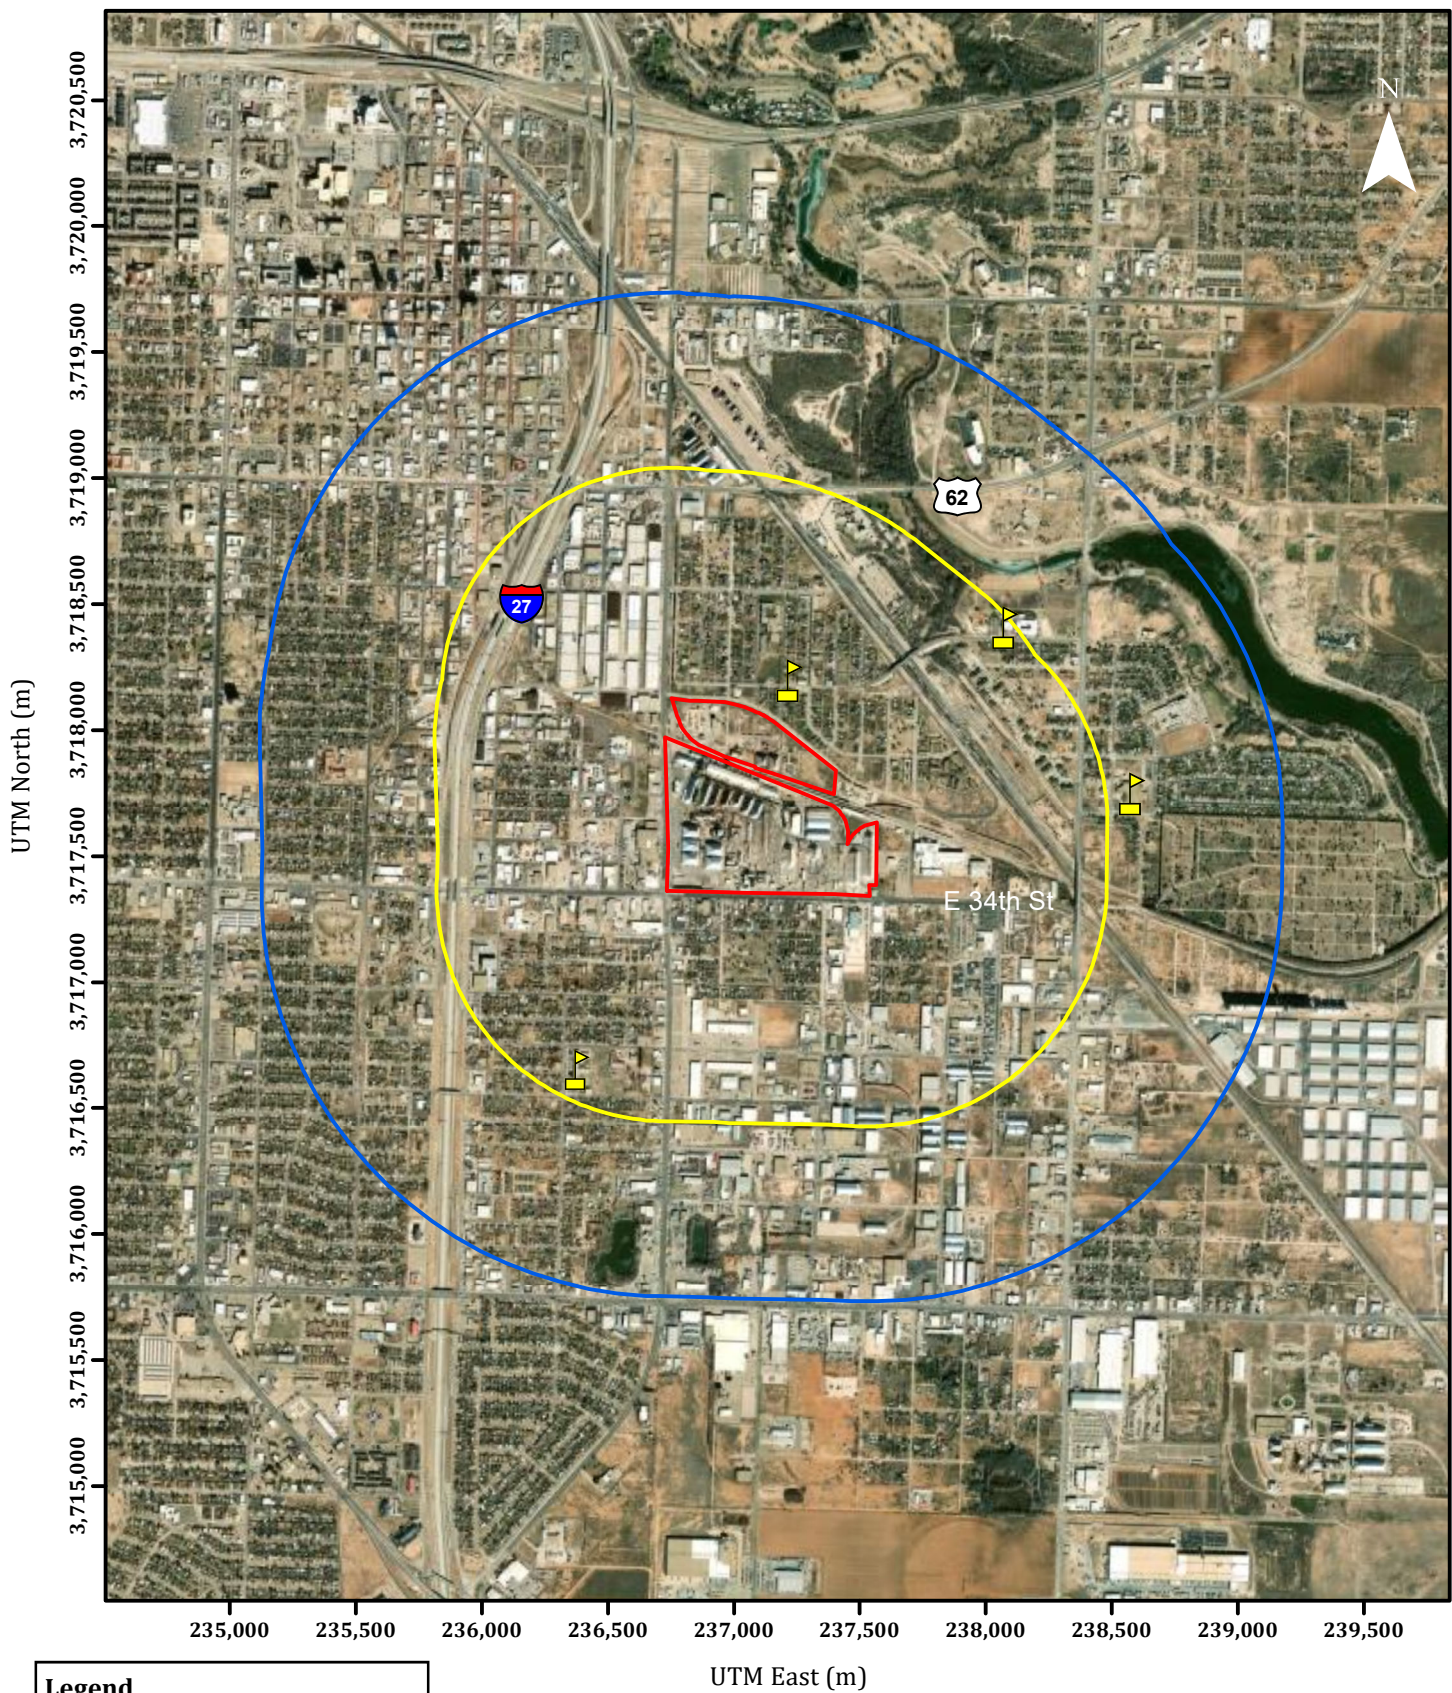

30 TAC §122.602 specifies that PM may be required for any emission unit included in the SOP that is subject to an emission limitation or standard contained in an applicable requirement, with exceptions listed in 30 TAC §122.602(b). Per 30 TAC §122.602(b)(1), PM requirements do not apply to emissions units subject to a MACT proposed after November 15, 1990. Accordingly, no PM requirements are proposed for the solvent extraction plant (PRO-SEP-1) subject to MACT GGGG, as it was proposed on April 12, 2001; and no PM requirements are proposed for the site's natural gas-fired boilers (BB-03, BB-04, CW-01, and FB-05) subject to MACT DDDDD, as it was proposed on January 13, 2003.

Per 30 TAC §122.602(a), PM requirements do not apply to emission units at a site that are not subject to an emission limitation or standard in an applicable requirement. Accordingly, no PM requirements are proposed for the site's natural gas-fired boilers (BB-03, BB-04, CW-01, and FB-05) under NSPS Subpart Dc or 30 TAC §112.

4.2 Compliance Assurance Monitoring

Compliance assurance monitoring may be required under 30 TAC §122.604 for each unit that has a standard or an emission limit in an applicable requirement, is controlled by a control device, and has pre-controlled emissions greater than Title V major source thresholds, with exceptions. None of the emissions units at the Avenue A Facility meet all of these criteria; therefore, CAM is not applicable to the sources at this site.
