E-mail: tmdl@tceq.texas.gov

TMDL project reports are available on the TCEQ website at:
<www.tceq.texas.gov/waterquality/tmdl/>

The preparation of this report was financed in part through grants from
the U.S. Environmental Protection Agency.

This TMDL report is based in large part on the report titled:
for Indicator Bacteria in the Watersheds of the Mission and Aransas Rivers”
prepared by the Texas Institute for Applied Environmental Research.

In compliance with the Americans with Disabilities Act, this document may be requested in
alternate formats by contacting the TCEQ at 512/239-0028,
Fax 239-4488, or 1-800-RELAY-TX (TDD), or by writing to
P.O. Box 13087, Austin, TX 78711-3087.

Two TMDLs for Bacteria in the Tidal Segments of the Mission and Aransas Rivers

Executive Summary

This document describes total maximum daily loads (TMDLs) for the tidal segments of the Mission and Aransas Rivers where concentrations of indicator bacteria exceed the criteria used to evaluate attainment of the contact recreation use. The Texas Commission on Environmental Quality (TCEQ) first identified the bacteria impairments within the Mission River Tidal and Aransas River Tidal segments in 2004. The segments have been identified as impaired in each subsequent edition of the Texas Integrated Report of Surface Water Quality (formerly called the Texas Water Quality Inventory and 303(d) List) through 2014. The impaired segments and their identifying assessment units (AUs) are:

- Mission River Tidal 2001_01;
- Aransas River Tidal 2003_01;

The Mission and Aransas Rivers are located in the Texas coastal plain, southeast of the city of San Antonio. Both rivers flow into Copano Bay, which is located on the mid-Texas Gulf Coast between San Antonio Bay and Corpus Christi Bay. Segments 2001 and 2003 are the portions of the Mission and Aransas Rivers, respectively, that are influenced by tidal action and, in addition to freshwater flow from their respective watersheds, also receive regular inflows of saline water from Copano Bay.

Twelve facilities in the Mission and Aransas watersheds treat domestic wastewater; three are in the Mission River watershed and nine are within the more populated Aransas River watershed. None of the wastewater treatment facilities (WWTFs) in the watersheds discharge directly into either the impaired Mission River Tidal or Aransas River Tidal segments.

No municipal separate storm sewer system (MS4) permits are held in the watersheds of the Mission and Aransas Rivers. A review of active stormwater general permits coverage (TCEQ, 2008) in the Mission River watershed, as of March 26, 2013, found four active industrial multi-sector general permit (MSGP) facilities and three active construction sites. A review of active stormwater general permits coverage in the Aransas River watershed, as of March 26, 2013, found seven active industrial MSGP facilities, eight active construction sites, and one active concrete production facility. Regulated stormwater comprises only a very
small portion of the areas of the subject watersheds - 0.06% for Mission River watershed and 0.04% for Aransas River watershed.

The discharges authorized by the industrial MSGP and construction stormwater permits are considered intermittent and variable (subject to precipitation and runoff), and no flow limit is specified in the permit authorizations. Given the circumstances of the permits, these outfalls are treated as part of the regulated stormwater discharge in the waste load allocations (WLAs).

*Escherichia coli* (*E. coli*) are widely used as an indicator bacteria to assess attainment of the contact recreation use in freshwater bodies, while Enterococci are used as the indicator bacteria in salt waters. Enterococci are the relevant indicator for the Mission River Tidal and Aransas River Tidal. The criteria for assessing attainment of the contact recreation use are expressed as the number (or “counts”) of Enterococci bacteria, typically given as the most probable number (MPN). The primary contact recreation use is not supported when the geometric mean of all Enterococci samples exceeds 35 MPN per 100 milliliters (mL).

Recent environmental monitoring within the Mission and Aransas Tidal segments has occurred at three TCEQ monitoring stations. Enterococci data collected at these stations over the seven-year period of December 1, 2003 through November 30, 2010 were used in assessing attainment of the primary contact recreation use as reported in the 2012 Texas Integrated Report (TCEQ, 2013). The 2012 assessment data indicate non-support of the primary contact recreation use because geometric mean concentrations exceed the geometric mean criterion of 35 MPN/100 mL for Mission River Tidal (66.70 MPN/100 mL) and Aransas River Tidal (60.40 MPN/100 mL).

A modified load duration curve (LDC) analysis was used to quantify allowable pollutant loads and specific TMDL allocations for point and nonpoint sources of indicator bacteria. The WLA for WWTFs was established as the full permitted discharge flow rate multiplied by the instream geometric criterion and also reduced to account for the required margin of safety (MOS). Future growth of existing or new domestic point sources was determined using population projections.

The TMDL calculations in this report will guide determination of the assimilative capacity of each stream under changing conditions, including future growth. Wastewater discharge facilities will be evaluated case by case.

The endpoint for the TMDLs in this report is to maintain concentrations of Enterococci below the geometric mean criterion of 35 MPN/100 mL. This endpoint was applied to both AUs addressed by the TMDL. This endpoint is identical to the geometric mean criterion for primary contact recreation in the 2014 Texas Surface Water Quality Standards (TSWS, 2014).
Introduction

Section 303(d) of the federal Clean Water Act requires all states to identify waters that do not meet, or are not expected to meet, applicable water quality standards. States must develop a TMDL for each pollutant that contributes to the impairment of a listed water body. The TCEQ is responsible for ensuring that TMDLs are developed for impaired surface waters in Texas.

A TMDL is like a budget—it determines the amount of a particular pollutant that a water body can receive and still meet its applicable water quality standards. TMDLs are the best possible estimates of the assimilative capacity of the water body for a pollutant under consideration. A TMDL is commonly expressed as a load with units of mass per period of time, but may be expressed in other ways.

The TMDL Program is a major component of Texas’ overall process for managing the quality of its surface waters. The program addresses impaired or threatened streams, reservoirs, lakes, bays, and estuaries (water bodies) in, or bordering on, the state of Texas. The primary objective of the TMDL Program is to restore and maintain the beneficial uses—such as drinking water supply, recreation, support of aquatic life, or fishing—of impaired or threatened water bodies.

This TMDL addresses impairments to the contact recreation use due to indicator bacteria in the Mission River Tidal and Aransas River Tidal segments. This TMDL takes a watershed approach to addressing indicator bacteria impairments. While TMDL allocations were developed only for the impaired AUs identified in this report, the entire project watershed and all WWTFs that discharge within it are included within the scope of this TMDL.

Section 303(d) of the Clean Water Act and the implementing regulations of the U.S. Environmental Protection Agency (EPA) in Title 40 of the Code of Federal Regulations (CFR), Part 130 (40 CFR 130) describe the statutory and regulatory requirements for acceptable TMDLs. The EPA provides further direction in its Guidance for Water Quality-Based Decisions: The TMDL Process (EPA, 1991). This TMDL document has been prepared in accordance with those regulations and guidelines.

The TCEQ must consider certain elements in developing a TMDL. They are described in the following sections of this report:

- Problem Definition
- Endpoint Identification
- Source Analysis
- Linkage Analysis
- Margin of Safety
- Pollutant Load Allocation
Seasonal Variation
Public Participation
Implementation and Reasonable Assurance

Upon adoption of the TMDL report by the TCEQ and subsequent EPA approval, these TMDLs will become an update to the state’s Water Quality Management Plan (WQMP).

Problem Definition

The TCEQ first identified the bacteria impairments to the Mission River Tidal and Aransas River Tidal segments in 2004. The segments have been identified as impaired in each subsequent edition of the Texas Integrated Report of Surface Water Quality (formerly called the Texas Water Quality Inventory and 303(d) List) through 2014.

This TMDL document will consider bacteria impairments in the two tidal segments, each of which has a single AU (Figure 1). The complete list of water bodies and their identifying AU numbers is shown below:

- Mission River Tidal 2001_01;
- Aransas River Tidal 2003_01

Because the two impaired segments each comprise only one AU, the AU descriptor (_01) is unnecessarily cumbersome. From this point forward, AU and segment may be used interchangeably. For example, the Mission River Tidal may be referred to as AU 2001_01 or Segment 2001, with each term referring to the same geographic unit.

Ambient Indicator Bacteria Concentrations

Recent environmental monitoring within the Mission River Tidal and Aransas River Tidal segments has occurred at three TCEQ monitoring stations (Figure 1). Enterococci data collected at these stations over the seven-year period of December 1, 2003 through November 30, 2010 were used in assessing attainment of the primary contact recreation use as reported in the 2012 Texas Integrated Report (TCEQ, 2013) and as summarized in Table 1. The 2012 assessment data indicate non-support of the primary contact recreation use because geometric mean concentrations of indicator bacteria exceed the geometric mean criterion of 35 MPN/100 mL for the Mission River Tidal (2001) and Aransas River Tidal (2003).

Watershed Overview

The Mission and Aransas Rivers, located adjacent to each other along the Texas Gulf Coast, are both comprised of two segments – the upstream segment of each river, designated as “Above Tidal,” and the downstream segment designated simply as “Tidal.” The above tidal portions of both the Mission and Aransas Rivers are perennial freshwater streams, while the downstream tidal portions are influenced by seawater from Mission and Copano Bays. This study incorporates a watershed approach where the entire drainage area of each river is considered (Figure 1).

The Mission River Above Tidal (Segment 2002) begins at the confluence of the Blanco and Medio Creeks in Refugio County and is approximately 11 miles in length. Mission River Tidal (Segment 2001) begins downstream of US 77 in Refugio County and flows approximately 16 miles into Mission Bay. Because of the contiguousness of these segments and the upstream position of Segment 2002 to the bacterially impaired Segment 2001, both water bodies are considered in this report. The TMDL development, however, will only be for Segment 2001. At its mouth, the Mission River drains an area of approximately 1,029 square miles in Bee (36% of the watershed), Refugio (31%), Goliad (30%), and Karnes (3%) counties (Figure 1).

The Aransas River above Tidal (Segment 2004) begins at the confluence of Poesta and Aransas Creeks in Bee County and is approximately 35 miles in length. The Aransas River Tidal (Segment 2003) begins upstream of US 77 on the Refugio/San Patricio County line, and flows approximately 28 miles into Copano Bay. At its mouth, the Aransas River drains an area of approximately 843 square miles in Bee (48% of the watershed), San Patricio (47%), Refugio (4%), Live Oak (0.6%) and Aransas (0.2%) counties (Figure 1). For the same reason as for the Mission River, both Segments 2003 and 2004 are described in this report, but the TMDL development is only for Segment 2003.
Two TMDLs for Bacteria in the Mission and Aransas Rivers, Segments 2001 and 2003

The 2012 Texas Integrated Report of Surface Water Quality (TCEQ, 2013) provides the following segment and AU descriptions for the water bodies considered in this document:

- **Segment 2001 (AU 2001_01) (Mission River Tidal)** - From the confluence with Mission Bay in Refugio County to a point 7.4 kilometers (4.6 miles) downstream of US 77 in Refugio County.
- **Segment 2002 (AU 2002_01) (Mission River Above Tidal)** - From a point 7.4 km (4.6 miles) downstream of US 77 in Refugio County to the confluence of Blanco Creek and Medio Creek in Refugio County.
- **Segment 2003 (AU 2003_01) (Aransas River Tidal)** - From the confluence with Copano Bay in Aransas/Refugio County to a point 1.6 kilometers (1.0 mile) upstream of US 77 in Refugio/San Patricio County.
- **Segment 2004 (AU s 2004_01 and 02)(Aransas River Above Tidal)** - From a point 1.6 kilometers (1.0 mile) upstream of US 77 in Refugio/San Patricio County to the confluence of Poesta Creek and Aransas Creek in Bee County.
- **Segment 2004A (AU 2004A_01) (Aransas Creek [unclassified water body])** - From confluence with the Aransas River to the headwaters of the stream about 10 km upstream of US Highway 59.
- **Segment 2004B (AUs 2004B_01 and 02) (Poesta Creek [unclassified water body])** - From the confluence with the Aransas River to the headwaters of the stream about 7.5 km upstream of FM 673.

**Watershed Climate and Hydrology**

The watersheds of the Mission and Aransas Rivers (henceforth collectively referred to as the Mission and Aransas watersheds) are in the approximate boundary area between climate regions (Larkin & Bomar, 1983). The region’s subtropical climate is caused by the “predominant onshore flow of tropical maritime air from the Gulf of Mexico,” while the increasing moisture content (from west to east) reflects variations in “intermittent seasonal intrusions of continental air” (Larkin & Bomar, 1983). For the period from 1981 – 2010, average annual precipitation in the Mission River watershed was 33.2 inches, slightly higher than the average annual total precipitation for the Aransas River watershed of 32.3 inches (Figure 2; PRISM, 2012). In Beeville, the location of the meteorological station most representative of the Aransas River watershed, the wettest month is normally September (3.8 in), and the driest month is normally February (1.6 inches), although some rainfall typically occurs year-round (NOAA, 2012).

In Beeville, average high temperatures generally reach their peak of 95°F in August, but highs above 100°F have occurred from April through September. Fair skies generally accompany the highest temperatures of summer when nightly average lows drop to about 72°F. During winter, the average low temperature is 43°F in January, although below freezing temperatures have occurred from September through April. The frost-free period in Beeville generally lasts for about...
287 days, with the average last frost occurring February 23 and the average first frost occurring on December 7 (Welsh, 2007).

**Watershed Population and Population Projections**

According to the 2010 Census (USCB, 2012), population throughout the Mission River watershed is generally rural and dispersed outside of the cities of Refugio (population 2,890) and Woodsboro (1,512). The total population of the Mission River watershed was approximately 8,882, indicating a population density of about 9 people per square mile. The largest municipalities within the more populous Aransas River watershed are the cities of Beeville (population 12,863), Sinton (5,665), Taft (3,048), and Odem (2,389). The total population of the Aransas watershed was approximately 45,689, indicating a population density of about 54 people per square mile, more than six times that of the Mission River watershed (Figure 3).
Population projections developed by the Office of the State Demographer and the Texas Water Development Board (TWDB, 2013) indicate that the populations of the seven counties that are included within the Mission River and Aransas River watersheds (Aransas, Bee, Goliad, Karnes, Live Oak, Refugio, and San Patricio) are expected to increase by an average of 14.5% between 2010 and 2050. For the cities within the watershed, including Beeville, Odem, Refugio, Sinton, Taft, and Woodsboro, the populations are projected to increase by an average of 13.5% between 2010 and 2050 (Table 2). The cities of Odem, Sinton, and Taft, all located within the Aransas River Tidal watershed, are expected to have the most significant growth (Table 2).

Land Use

The land use/land cover data for the watersheds of the Aransas and Mission Rivers were obtained from the 2006 National Land Cover Database (NCDC - U.S. Geological Survey) and are displayed in Figure 4. The land use/land cover is represented by the following categories and definitions:

**Scrub/Grassland** - Areas dominated by shrubs; less than 5 meters tall with shrub canopy typically greater than 20% of total vegetation. **Grassland**: Areas dominated by grammanoid or herbaceous vegetation, generally greater than 80% of total vegetation. These areas are not subject to intensive management such as tilling, but can be utilized for grazing.

**Pasture** - Areas of grasses, legumes, or grass-legume mixtures planted for livestock grazing or the production of seed or hay crops, typically on a perennial cycle. Pasture/hay vegetation accounts for greater than 20% of total vegetation.

**Cultivated Crops** - Areas used for the production of annual crops such as corn, soybeans, vegetables, tobacco, and cotton, and also perennial woody crops such as orchards and vineyards. Crop vegetation accounts for greater than 20% of total vegetation. This class also includes all land being actively tilled.

**Developed** - Includes areas of constructed materials (residential/commercial), impervious surfaces, parks, and golf courses. Impervious surfaces account for 20 to 100% of total cover.

**Forest** - Areas dominated by trees generally greater than 5 meters tall, and greater than 20% of total vegetation cover. Includes deciduous and evergreen species.
Figure 4. 2006 land use/land cover within the watersheds of the Mission and Aransas Rivers.

Source: USGS (2011)

Wetlands - Areas where forest, shrubland vegetation and/or perennial herbaceous vegetation accounts for greater than 20% of vegetative cover and the soil or substrate is periodically saturated with or covered with water.

Barren Land (Rock/Sand/Clay) - Barren areas of bedrock, desert pavement, scarps, talus, slides, volcanic material, glacial debris, sand dunes, strip mines,
gravel pits, and other accumulations of earthen material. Generally, vegetation accounts for less than 15% of total cover.

**Open Water** - All areas of open water, generally with less than 25% cover of vegetation or soil.

As displayed in Table 3, the watershed area encompassing Segments 2001 and 2002 (Mission River watershed) is 658,581 acres. Dominant land uses in the Mission River watershed include Scrub/Grassland (47.3%) and Pasture (31.5%). The watershed area encompassing Segments 2003 and 2004 (Aransas River watershed) is 539,714 acres, and is dominated by Cultivated Crops (44.7%) and Scrub/Grassland (24.3%). Both watersheds are mostly rural, with only about 5% of the combined area classified as Developed.

Note: NLCD is the National Land Cover Database.
Endpoint Identification

All TMDLs must identify a quantifiable water quality target that indicates the desired water quality condition and provides a measurable goal for the TMDL. The TMDL endpoint also serves to focus the technical work to be accomplished and as a criterion against which to evaluate future conditions.

The endpoint for the TMDLs in this report is to maintain concentrations of Enterococci below the geometric mean criterion of 35 MPN/100 mL. This endpoint was applied to both AUs addressed by the TMDL. This endpoint is identical to the geometric mean criterion for primary contact recreation in the 2010 Surface Water Quality Standards (TCEQ, 2010).

Source Analysis

Pollutants may come from several sources, both regulated and unregulated. Regulated pollutants, referred to as “point sources,” come from a single definable point, such as a pipe, and are regulated by permit under the Texas Pollutant Discharge Elimination System (TPDES) or the National Pollutant Discharge Elimination System (NPDES). WWTF and storm water discharges from industries, construction, and the MS4s of cities are considered point sources of pollution.

Unregulated sources are typically nonpoint source in origin, meaning the pollutants originate from multiple locations and rainfall runoff washes them into surface waters. Nonpoint sources are not regulated by permit.

With the exception of WWTFs, which receive individual WLAs (see the “Waste Load Allocation” section), the regulated and unregulated sources in this section are presented to give a general account of the different sources of bacteria expected in the watershed. These are not meant to be used for allocating bacteria loads or interpreted as precise inventories and loadings.

Regulated Sources

Regulated sources are controlled by permit under the TPDES and the NPDES programs. The permitted sources in the TMDL watersheds include WWTF outfalls and stormwater discharges from industry and construction.

Domestic Wastewater Treatment Facilities

Twelve facilities in the Mission River and Aransas River watersheds treat domestic wastewater; three are in the Mission River watershed and nine are within the more populated Aransas River watershed (Table 4; Figure 5). None of the WWTFs in the watersheds discharge directly into either the Mission River Tidal or Aransas River Tidal segments, which are the subjects of this TMDL document. The only WWTF that discharges directly into a main stem river is the Chase Field WWTF operated
by the City of Beeville, which discharges into the Aransas River Above Tidal (Segment 2004). All other WWTFs discharge into tributaries of the impaired rivers or to ditches that eventually flow into the impaired rivers or Copano Bay.

**Review of Compliance Information on Permitted Sources**

A review of the EPA Enforcement & Compliance History Online (ECHO) database (EPA, 2013a), conducted April 17, 2013, revealed non-compliance issues regarding *E. coli* permit limits for four WWTFs in the Mission River and Aransas River watersheds (See Table 5).

* No compliance data was available through ECHO for Chase Field WWTF.
For the period from July 2009 through December 2012, the following four facilities reported exceedances in bacteria concentration discharge limits:

- City of Beeville - Moore Street WWTF,
- City of Sinton - Rod and Bessie Welder WWTF,
- TxDOT- Sinton Engineering Building WWTF, and
- Town of Woodsboro WWTF.

None of the bacteria effluent violations were reported as Significant Non-compliance (SNC) effluent violations, but unresolved SNC violations for bacteria were indicated for the following three facilities:

- City of Sinton - Rod and Bessie Welder WWTF,
- TxDOT- Sinton Engineering Building WWTF, and
- Town of Woodsboro WWTF.

Two of the 12 permits do not require monitoring bacteria concentrations in effluent; those are the City of Sinton- Main WWTF and the Skidmore Water Supply Corporation (WSC) WWTF. For the City of Beeville - Chase Field WWTF, *E. coli* monitoring is a permit requirement, but no *E. coli* data were available through ECHO when that database was searched.

Bacteria data were collected under a special study by the Nueces River Authority (NRA) (Nueces River Authority, 2011). The NRA sampled the effluent from 12 WWTFs over a period from October 2007 to January 2011. A summary of bacteria sampling data collected at the ten WWTF outfalls that were located within the Mission River and Aransas River watersheds is presented in Table 6. (The City of Odem outfall and the City of Bayside are both outside of the subject watersheds, and therefore were not included in the following table.) The data indicate that most WWTFs were providing disinfected effluent with indicator bacteria levels below state instream indicator bacteria criteria, though the data indicate that two facilities (City of Sinton - Main and St. Paul WSC) exceeded the criteria for one or both indicator bacteria more than 50% of the time.

**TPDES General Wastewater Permits**

In addition to the individual wastewater discharge permits listed in Table 4, discharges of processed wastewater from certain types of facilities are required to be covered by one of several TPDES general permits:

- TXG110000 – concrete production facilities
- TXG130000 – aquaculture production facilities
- TXG340000 – petroleum bulk stations and terminals
- TXG670000 – hydrostatic test water discharges
- TXG830000 – water contaminated by petroleum fuel or petroleum substances
Two TMDLs for Bacteria in the Mission and Aransas Rivers, Segments 2001 and 2003

- TXG920000 – concentrated animal feeding operations
- WQG20000 – livestock manure compost operations (irrigation only)

Table 6. Summary of Enterococci and *E. coli* WWTF effluent data collected by NRA from October 2007 to January 2011.

*Number of Samples

A review of active general permit coverage (TCEQ, 2008) in the Mission River watershed as of 26 March 2013 found no operations or facilities of the types listed. A review of active general permit coverage (TCEQ, 2008) in the Aransas River watershed as of 26 March 2013 found one concrete production facility covered by the general permit. This facility is located in Segment 2004, above the impaired AU watershed. No other active general wastewater permit facilities or operations were found. There were no facilities covered under the general permits for aquaculture production, petroleum bulk stations and terminals, hydrostatic test
water discharges, water contaminated by petroleum fuel or petroleum substances, concentrated animal feeding operations, or livestock manure compost operations. No attempt was made to allocate bacteria loads to the concrete production facility in Segment 2004, Aransas River Above Tidal, because (1) flows are intermittent and variable and (2) the flows are not anticipated to contain high bacteria loadings.

**Sanitary Sewer Overflows**

Sanitary sewer overflows (SSOs) are unauthorized discharges that must be addressed by the responsible party, either the TPDES permittee or the owner of the collection system that is connected to a permitted system. SSOs in dry weather most often result from blockages in the sewer collection pipes caused by tree roots, grease, and other debris. Inflow and infiltration (I/I) are typical causes of SSOs under conditions of high flow in the WWTF system. Blockages in the line may exacerbate the I/I problem. Other causes, such as a collapsed sewer line, may occur under any condition.

The TCEQ Region 14 Office maintains a database of SSO data reported by municipalities. These SSO data typically contain estimates of the total gallons spilled, responsible entity, and a general location of the spill. The reports of SSO events that occurred within the watersheds of the Mission and Aransas Rivers between August 2009 and January 2013 are shown in Table 7. Ten separate incidences were reported for four different facilities. The reported data indicate that the SSOs occurred at various times of the year and, of the incidences in which duration and volume were reported, the durations lasted from one minute to almost 44 hours, and overflow volumes ranged from less than one gallon to 28,200 gallons.

**TPDES-Regulated Stormwater**

When evaluating stormwater for a TMDL allocation, a distinction must be made between stormwater originating from an area under a TPDES or NPDES-regulated discharge permit and stormwater originating from areas not under a TPDES or NPDES-regulated discharge permit. Stormwater discharges fall into two categories:

1) Stormwater subject to regulation, which is any stormwater originating from TPDES-regulated MS4s, industrial facilities, and regulated construction activities.

2) Stormwater runoff not subject to regulation.

Discharges of stormwater from a Phase II urbanized area, industrial facility, construction site, or other facility involved in certain activities are required to be covered under the following TPDES general permits:

- TXR040000 – stormwater Phase II MS4 general permit for urbanized areas
Two TMDLs for Bacteria in the Mission and Aransas Rivers, Segments 2001 and 2003

- TXR050000 – stormwater MSGP for industrial facilities
- TXR150000 – stormwater from construction activities disturbing more than one acre
- TXG110000 – concrete production facilities
- TXG340000 – petroleum bulk stations and terminals

</table>

Three of these permits (MS4, MSGP, and construction) pertain solely to stormwater discharges. The other two – concrete production facilities and petroleum bulk stations and terminals – also authorize the discharge of process wastewater as discussed under “TPDES General Wastewater Permits.”

A review of active stormwater general permits coverage (TCEQ, 2008) in the Mission River watershed, as of March 26, 2013, found four active industrial (MSGP) facilities and three active construction sites. A review of active stormwater general permits coverage in the Aransas River watershed, as of March 26, 2013, found seven active industrial (MSGP) facilities, eight active construction sites, and one active concrete production facility. There are currently no Phase II MS4s or petroleum bulk station and terminal facilities in either watershed. Regulated
stormwater comprises only a very small portion of the areas of the subject watersheds — 0.06% for Mission River watershed and 0.04% for Aransas River watershed.

**Illicit Discharges**

Pollutant loads can enter streams from outfalls that are authorized by law, for example under the provisions of a permit granted by the appropriate regulatory entity, but they can also enter streams from unauthorized sources. The term “illicit discharge” refers to an unauthorized release of pollutants either because it is not allowed by law or because the release requires authorization from a permitting entity. Illicit discharges can be categorized as either direct or indirect. Examples of illicit discharges can be found in the *Illicit Discharge Detection and Elimination Manual: A Handbook for Municipalities* (NEIWPCC, 2003) and include the following:

**Examples of Direct Illicit Discharges:**

- sanitary wastewater piping that is directly connected from a home to the storm sewer;
- materials that have been dumped illegally into a storm drain catch basin;
- a shop floor drain that is connected to the storm sewer; and
- a cross-connection between the sanitary sewer and storm sewer systems.

**Examples of Indirect Illicit Discharges:**

- an old and damaged sanitary sewer line that is leaking fluids into a cracked storm sewer line; and
- a failing septic system that is leaking into a cracked storm sewer line or causing surface discharge into the storm sewer.

**Unregulated Sources**

Unregulated sources of indicator bacteria are generally nonpoint sources. Nonpoint source (NPS) loading enters the impaired segment through distributed, nonspecific locations, which may include urban runoff not covered by a permit, wildlife, various agricultural activities, agricultural animals, land application fields, failing on-site sewage facilities (OSSFs), unmanaged and feral animals, and domestic pets.

**Wildlife and Unmanaged Animal Contributions**

Enterococci bacteria are common inhabitants of the intestines of all warm blooded animals, including wildlife such as mammals and birds. In developing bacteria TMDLs, it is important to identify by watershed the potential for bacteria
contributions from wildlife. Wildlife are naturally attracted to riparian corridors of streams and rivers. With direct access to the stream channel, the direct deposition of wildlife waste can be a concentrated source of bacteria loading to a water body. Fecal bacteria from wildlife are also deposited onto land surfaces, where they may be washed into nearby streams by rainfall runoff. An estimate of deer and feral hog populations for the watersheds of the Mission and Aransas Rivers were made by Borel & Karthikeyan (2013) and are reported in Table 8.

On-Site Sewage Facilities
For each of the four major watersheds (Aransas River Above Tidal, Aransas River Tidal, Mission River Above Tidal, and Mission River Tidal), the number of OSSFs was estimated from information in Borel & Karthikeyan (2013) and personal communications with Borel in April 2014. Table 9 shows the estimated total numbers of OSSFs by the four major watersheds and the estimated total number of failing OSSFs based on soil limitation class and failure rates. More detail on the soil limitation class and failure rates is provided in Borel & Karthikeyan (2013).

Non-Permitted Agricultural Activities and Domesticated Animals

Domesticated animal populations for goats, horses, sheep, and cattle in the Mission River and Aransas River watersheds were estimated based on Borel & Karthikeyan (2013). The animal numbers distributed to the four watersheds are presented in Table 10. Activities, such as livestock grazing close to water bodies and the use of manure as fertilizer, can contribute fecal indicator bacteria such as Enterococci to nearby water bodies. The livestock numbers in Table 10 are provided to demonstrate that livestock are a potential source of bacteria in the watershed. These livestock numbers, however, are not used to develop an allocation of allowable bacteria loading to livestock. The estimated livestock populations were verified by the Texas State Soil and Water Conservation Board.

Pets can also be sources of Enterococci, because storm runoff carries the animal wastes into streams (EPA, 2013b). The estimated number of domestic dogs in the Mission River and Aransas River watersheds was estimated by Borel & Karthikeyan (2013), and is shown in Table 11.

Bacteria Survival and Die-off

Bacteria are living organisms that survive and die in the environment. Certain enteric bacteria can survive and replicate in organic materials if appropriate conditions prevail (e.g., warm temperature and moist conditions). Fecal organisms from improperly treated effluent can survive and replicate during their transport in pipe networks, and they can survive and replicate in organic rich materials such as compost and sludge. While the die-off of indicator bacteria has been demonstrated in natural water systems due to the presence of sunlight and predators, the potential for their re-growth is less well understood. Both processes (replication and die-off) are instream processes and are not considered in the bacteria source loading estimates of each water body in the TMDL watersheds.

Linkage Analysis

Establishing the relationship between instream water quality and the source of loadings is an important component in developing a TMDL. It allows for the evaluation of management options that will achieve the desired endpoint. The relationship may be established through a variety of techniques.

Generally, if high bacteria concentrations are measured in a water body at low to median flow in the absence of runoff events, the main contributing sources are likely to be point sources. During ambient flows, these constant inputs to the system will increase pollutant concentrations depending on the magnitude and concentration of the sources. As flows increase in magnitude, the impact of point sources is typically diluted, and would therefore be a smaller part of the overall concentrations.

Bacteria load contributions from regulated and unregulated stormwater sources are greatest during runoff events. Rainfall runoff, depending upon the severity of the storm, has the capacity to carry indicator bacteria from the land surface into the receiving stream. Generally, this loading follows a pattern of lower concentrations in the water body just before the rain event, followed by a rapid increase in bacteria concentrations in the water body as the first flush of storm runoff enters the receiving stream. Over time, the concentrations decline because the sources of indicator bacteria are attenuated as runoff washes them from the land surface and the volume of runoff decreases following the rain event.

Modified Load Duration Curve Analysis

A modified LDC method was used to examine the relationship between instream water quality and the source of indicator bacteria loads. LDCs are graphs of the frequency distribution of loads of pollutants in a stream. In the case of these TMDLs, the loads shown are of Enterococci bacteria in MPN/day. LDCs are derived from Flow Duration Curves (FDCs), which are graphs of the frequency
distribution of flow in a stream. The LDCs shown in the following figures represent the maximum acceptable load in the stream that will result in achievement of the TMDL water quality target.

LDCs are a simple statistical method that provides a basic description of the water quality problem. The strength of this tool is that it is easily developed and explained to stakeholders, and uses available water quality and flow data. The LDC method does not require any assumptions regarding loading rates, stream hydrology, land use conditions, and other conditions in the watershed.

Inherent to the use of LDCs as the mechanism of linkage analysis is the assumption of a one to one relationship between instream loadings and loadings originating from point sources and the landscape as regulated and unregulated sources. Further, this one to one relationship was also inherently assumed when using LDCs to define the TMDL pollutant load allocation (LA). That is, the allocation of pollutant loads was based on apportioning the loadings based on flows assigned to WWTFs, a fractional proportioning of the remaining flow based on the area of the watershed under stormwater regulation, and assigning the remaining portion to unregulated stormwater.

The State of Oregon Department of Environmental Quality (ODEQ) developed the modification of the LDC method (or modified LDC method) for tidal streams of the Umpqua River Basin (ODEQ, 2006) that was applied to the Mission River Tidal (Segment 2001) and Aransas River Tidal (Segment 2003).

The modified LDC method is based on the assumption that combining of river water with seawater increases the loading capacity in the tidal river because seawater typically contains lower concentrations of indicator bacteria, such as Enterococci, than river water. The assumption of decreasing concentrations of Enterococci with distance from the tidal segments of the Mission and Aransas River into Copano Bay are borne out in the historical data.

The weaknesses of the LDC method include the limited information it provides regarding the magnitude or specific origin of the various sources. Only limited information is gathered regarding point and nonpoint sources in the watershed. The general difficulty in analyzing and characterizing Enterococci in the environment is also a weakness of this method.

The modified LDC method allows for estimation of existing pollutant loads and TMDLs by utilizing the cumulative frequency distribution of stream flow with diluting seawater and measured pollutant concentration data (ODEQ, 2006). In addition to estimating instream loads, this method (1) allows for the determination of the hydrologic conditions under which impairments are typically occurring, (2) can give indications of the broad origins of the bacteria (i.e., point source and stormwater), and (3) provides a means to allocate allowable loadings.
Data requirements for the modified LDC method are minimal, consisting of continuous daily stream flow records and both historical bacteria and salinity data. A 15-year period of record from January 1, 1998 through December 31, 2012 was selected for LDC development, and this period included all available Enterococci data at the time of the study. A 15-year period is of sufficient duration to contain a reasonable variation from dry months and years to wet months and years and at the same time is short enough in duration to contain a hydrology that is responding to recent and current conditions in the watershed.

For this report, LDCs were constructed for the most downstream monitoring station within the Mission River Tidal (Station 12943) and the Aransas River Tidal (Station 12947). The most downstream surface water quality monitoring (SWQM) stations were selected because these locations encompass more of the drainage area of each watershed and are representative of conditions in a greater area of each watershed than stations located farther upstream.

On numerous creeks and rivers in Texas, U.S. Geological Survey (USGS) streamflow gauging stations have been in operation for a sufficient period to provide long-term streamflow records. The USGS streamflow gauges used for LDC development and the area of application are:

- USGS gauging station 08189500 (Mission River at Refugio, TX) applied to develop the freshwater flows for Mission River Tidal Station 12943; and
- USGS gauging station 08189700 (Aransas River near Skidmore, TX) applied to develop the freshwater flows for the Aransas River Tidal Stations 12947.

The required daily streamflow record for each LDC was estimated based on application of a drainage area ratio computed as the drainage area above the LDC location divided by the drainage area of the appropriate USGS gauge. Prior to application of the drainage area ratio, the USGS gauge record was corrected by removing (subtracting) upstream WWTF discharges based on discharge monitoring report (DMR) information. After multiplication of the corrected stream flow record by the drainage area ratio, a final adjustment occurred for the purposes of pollutant load computations. The hydrologic records were adjusted to reflect full permitted flows from all upstream WWTFs and future growth flows that account for the probability that additional flows from WWTF discharges may occur as a result of population increases.

Another part of the development of the modified LDC method is to determine a relationship of daily streamflow and measured salinities. The resulting regression is used to determine the daily volume of saltwater present for each daily freshwater flow in the 15-year period of record.

Information on the modified LDC method is provided in Appendix A and additional details are provided in the document titled Technical Support.
Two TMDLs for Bacteria in the Mission and Aransas Rivers, Segments 2001 and 2003

Each FDC was generated by:

- ranking the daily flow data, including any additional saltwater flow, from highest to lowest,
- calculating the percent of days each flow was exceeded (rank ÷ quantity of the number of data points + 1), and
- plotting each flow value (y-axis) against its exceedance value (x-axis).

Exceedance values along the x-axis represent the percent of days that flow was at or above the associated flow value on the y-axis. Exceedance values near 100% occur during low flow or drought conditions while values approaching 0% occur during periods of high flow or flood conditions.

Bacteria LDCs were developed by multiplying each streamflow value along the flow duration curves by the Enterococci geometric mean criterion (35 MPN/100 mL) and by the conversion factor to convert to loading in colonies per day. Flow was measured in cubic feet per second (cfs). This effectively displays the LDC as the TMDL curve of maximum allowable loading:

\[
\text{TMDL (MPN/day)} = \text{Criterion} \times \text{flow (cfs)} \times \text{conversion factor}
\]

Where:

\[
\text{Criterion} = 35 \text{ MPN/100 mL (Enterococci)}
\]

\[
\text{Conversion factor (to MPN/day)} = 283.168 \frac{100 \text{ mL}}{\text{ft}^3} \times 86,400 \text{ seconds/day}
\]

The resulting curve plots each bacteria load value (y-axis) against its exceedance value (x-axis). Exceedance values along the x-axis represent the percent of days that the bacteria load was at or above the allowable load on the y-axis.

For the LDCs at each of the two TCEQ monitoring stations, historical bacteria data obtained from the TCEQ Surface Water Quality Monitoring Information System (SWQMIS) database were superimposed on the allowable bacteria LDC. Each historical Enterococci measurement was associated with the flow on the day of measurement and converted to a bacteria load. The associated flow for each bacteria loading was compared to the FDC data to determine its value for “percent days flow exceeded,” which becomes the “percent of days load exceeded” value for purposes of plotting the Enterococci loading. Each load was then plotted on the LDC at its percent exceedance. This process was repeated for each Enterococci measurement at each station. Points above the LDC represent exceedances of the bacteria criterion and their associated allowable loadings. As a further refinement, the historical Enterococci points on the LDCs were symbolized according to
whether the sampling event was considered to be a wet or non-wet weather event based on antecedent rainfall. A sample was determined to be influenced by a wet weather event based on the reported “days since last precipitation” (DSLP). Wet weather events were determined by DSLP of 0-3.

The flow exceedance frequency can be subdivided into hydrologic condition classes to facilitate the diagnostic and analytical uses of FDCs and LDCs. The hydrologic classification scheme utilized for the TMDL watersheds is as follows: high flow regime (0 – 10%), mid-range flow regime (10 – 60%), and low flow regime (60 – 100%). Additional information explaining the LDC method and the modified LDC method may be found in Cleland (2003), Nevada Department of Environmental Protection (NDEP 2003), and ODEQ (2006).

The median loading of the high flow regime (0-10% exceedance) is used for the TMDL calculations. The median loading of the high flow regime is represented by the 5% exceedance and is used for the TMDL calculations, because it represents a reasonable yet high value for the allowable pollutant load allocation.

An important observation is that under the high flow regime used for the TMDL calculations, there was no seawater volume computed as being present at the two locations where LDCs were developed. Saltwater has been effectively pushed out of the rivers by the freshwater inflows present under the high flow regime. With an absence of seawater at these high flows, the modified LDC results effectively simplified to those of the LDC method without any adjustments to accommodate tidal influences.

**Load Duration Curve Results**

For developing the TMDL allocation, LDCs were constructed for the most downstream monitoring station within the Mission River Tidal and Aransas River Tidal (Figures 6 and 7). Geometric mean loadings for the data points within each flow regime have also been distinguished on each figure to aid interpretation. The LDCs for the two monitoring stations provide a means of identifying the stream flow conditions under which exceedances in Enterococci concentrations have occurred. The LDCs depict the allowable loadings at the stations under the geometric mean criterion (35 MPN/100 mL) and show that existing loadings often exceed the criterion. For purposes of the pollutant load computations, the hydrologic records for the FDCs and subsequent allowable loads from the LDCs are adjusted to reflect future capacity estimates that account for the probability that additional flows from WWTF discharges may occur as a result of future population increases in the TMDL watersheds.

Based on these LDCs with historical Enterococci data added to the graphs (Mission River Tidal Station 12943, Figure 6 and Aransas River Tidal Station 12947, Figure 7), the following broad linkage statements can be made. For both the Mission River
and Aransas River watersheds, the historical Enterococci data indicate that elevated bacteria loadings occur under all flow conditions, but become most elevated under the highest flows and are often below the geometric mean criterion under the lowest flows. Regulated stormwater comprises only a very small portion of the watershed (0.06% for the Mission River watershed and 0.04% for the Aransas River watershed) and must be considered only a minor contributor. Unregulated stormwater most likely comprises the majority of high-flow related loadings. The elevated Enterococci loadings under the lower flow conditions cannot be reasonably attributed exclusively to WWTFs due to the fact that the outfalls are typically located at significant distances from the SWQM stations. Also, most of the WWTFs in the TMDL watersheds show a relatively good compliance record. Therefore, other sources of bacteria loadings under lower flows and in the absence of overland flow contributions (i.e., without stormwater contribution) are most likely contributing bacteria directly to surface water. Bacteria loading under lower flows could occur through direct deposition of fecal material from wildlife, feral hogs, and livestock. The actual contribution of bacteria loadings attributable to these direct sources of fecal material deposition cannot be determined using LDCs.

Figure 6. Load duration curve for Station 12943, Mission River Tidal.
Figure 7.  Load duration curve for Station 12947, Aransas River Tidal.

**Margin of Safety**

The MOS is used to account for uncertainty in the analysis used to develop the TMDL and thus provide a higher level of assurance that the goal of the TMDL will be met. According to EPA guidance (EPA, 1991), the MOS can be incorporated into the TMDL using two methods:

1) Implicitly incorporating the MOS using conservative model assumptions to develop allocations; or

2) Explicitly specifying a portion of the TMDL as the MOS and using the remainder for allocations.

The MOS is designed to account for any uncertainty that may arise in specifying water quality control strategies for the complex environmental processes that affect water quality. Quantification of this uncertainty, to the extent possible, is the basis for assigning a MOS.

The TMDLs covered by this report incorporate an explicit MOS by setting a target for indicator bacteria loads that is five percent lower than the geometric mean criterion. For primary contact recreation, this equates to a geometric mean target for Enterococci of 33.3 MPN/100 mL. The net effect of the TMDL with MOS is that the assimilative capacity or allowable pollutant loading of each water body is slightly reduced.
Pollutant Load Allocation

A TMDL represents the maximum amount of a pollutant that the stream can receive in a single day without exceeding water quality standards. The pollutant load allocations for the selected scenarios were calculated using the following equation:

\[ \text{TMDL} = \text{WLA} + \text{LA} + \text{FG} + \text{MOS} \]

Where:

- TMDL = total maximum daily load
- WLA = waste load allocation, the amount of pollutant allowed by existing regulated or permitted dischargers
- LA = load allocation, the amount of pollutant allowed by unregulated or non-permitted sources
- FG = loadings associated with future growth from potential permitted facilities
- MOS = margin of safety

As stated in 40 CFR, Section 130.2(1), TMDLs can be expressed in terms of mass per time, toxicity, or other appropriate measures. For Enterococci, TMDLs are expressed as MPN/day, and represent the maximum one-day load the stream can assimilate while still attaining the standards for surface water quality.

The TMDL component for the two impaired AUs covered in this report are derived using the median flow within the high flow regime (or 5% flow) of the LDC developed for the downstream SWQM station in each AU (12943 in the Mission River and 12947 in the Aransas River). The immediately following sections will present an explanation of the TMDL component first, followed by the results of the calculation for that component.

AU-Level TMDL Computations

The bacteria TMDLs for the Mission River Tidal and Aransas River Tidal segments were developed as a pollutant load allocation based on information from the most downstream LDCs (Figures 6 and 7). As discussed in more detail in Appendix A, bacteria LDCs using modifications to include tidal influences were developed by multiplying each flow value along the flow duration curves by the Enterococci criterion (35 MPN/100 mL) and by the conversion factor used to represent maximum loading in MPN/day. Effectively, the “Allowable Load” displayed in the modified LDC at 5% exceedance (the median value of the high-flow regime) is the TMDL:
TMDL (MPN/day) = Criterion * Flow (cfs) * Conversion factor

Where:

Criterion = 35 MPN/100 mL (Enterococci)

Conversion factor (to MPN/day) = 283.168 \frac{100\ mL}{ft^3} * 86,400 \ sec/day

At 5% load duration exceedance, the TMDL values are provided in Table 12.

**Margin of Safety**

The MOS is only applied to the allowable loading for a watershed. Therefore the margin of safety is expressed mathematically as the following:

$$MOS = 0.05 \times TMDL$$

Where:

$MOS = \text{margin of safety load}$

$TMDL = \text{total maximum allowable load}$

Since the MOS is based solely on the TMDL term, the calculation is straightforward (Table 13).

Table 13. MOS calculations for downstream stations within the Mission and Aransas Rivers.

**Waste Load Allocation**

The WLA consists of two parts – the waste load that is allocated to TPDES-regulated wastewater treatment facilities (WLA\textsubscript{WWTF}) and the waste load that is allocated to regulated stormwater dischargers (WLA\textsubscript{SW}).
Two TMDLs for Bacteria in the Mission and Aransas Rivers, Segments 2001 and 2003

\[ WLA = WLA_{WWTF} + WLA_{SW} \]

**WWTFs**

TPDES-permitted wastewater treatment facilities are allocated a daily waste load (WLA_{WWTF}) calculated as their full permitted discharge flow rate multiplied by the instream geometric criterion and also reduced to account for the required MOS. The saline water Enterococci criterion (35 MPN/100mL) is used as the WWTF target. The WLA_{WWTF} term is also calculated for the freshwater *E. coli* primary contract recreation geometric mean criterion of 126 MPN/100 mL, since WWTF bacteria permit limits are often expressed in terms of *E. coli*. This is expressed in the following equation:

\[ WLA_{WWTF} = \text{Criterion} \times \text{Flow} \times \text{Conversion Factor} \times (1 - F_{MOS}) \]

Where:

- **Criterion** = 35 MPN/100 mL for Enterococci; 126 MPN/100 mL for *E. coli*
- **Flow** = full permitted flow in millions of gallons per day (MGD)
- **Conversion Factor (to MPN/day)** = 1.54723 cfs/MGD * 283.168 mL/ft³ * 86,400 seconds/day
- **F_{MOS}** = fraction of loading assigned to margin of safety (5% or 0.05)

Thus the daily allowable loading of Enterococci and *E. coli* assigned to WLA_{WWTF} was determined based on the full permitted flow of each WWTF and summed individually for the watersheds of the Mission and Aransas Rivers. Table 14 presents the WLAs for each individual WWTF located within each of the two TMDL watersheds. The WLA_{WWTF} for each AU includes the sum of the WWTF allocations for all upstream AUs. Since the pollutant load allocation is developed in terms of Enterococci as the indicator bacteria, it is the Enterococci loadings from Table 14 that will be used in subsequent computations.

### Stormwater

Stormwater discharges from MS4, industrial, and construction areas are also considered permitted or regulated point sources. Therefore, the WLA calculations must also include an allocation for permitted stormwater discharges (WLA<sub>sw</sub>). A
simplified approach for estimating the WLA for these areas was used in the
development of these TMDLs due to the limited amount of data available, the
complexities associated with simulating rainfall runoff, and the variability of
stormwater loading.

The percentage of the land area included in each watershed that is under the
jurisdiction of stormwater permits is used to estimate the amount of the overall
runoff load that should be allocated as the permitted stormwater contribution in
the WLASW component of the TMDL. The LA component of the TMDL corresponds
to direct nonpoint runoff and is the difference between the total load from
stormwater runoff and the portion allocated to WLASW.

WLASW is the sum of loads from regulated stormwater sources and is calculated as
follows:

\[
WLASW = (TMDL - WLAWWTF - FG - MOS) \times FDA_{SWP}
\]

Where:

- \( WLASW \) = sum of all regulated stormwater loads
- \( TMDL \) = total maximum daily load
- \( WLAWWTF \) = sum of all WWTF loads
- \( FG \) = sum of future growth loads from potential permitted facilities
- \( MOS \) = margin of safety load
- \( FDA_{SWP} \) = fractional proportion of drainage area under jurisdiction of
  stormwater permits

In order to calculate the WLASW component of the TMDL, the fractional proportion
of the drainage area under the jurisdiction of stormwater permits (\( FDA_{SWP} \)) must
be determined in order to estimate the amount of overall runoff load that should
be allocated to WLASW. The term \( FDA_{SWP} \) was calculated based on the combined
area under regulated stormwater permits. As described in the Source Analysis
section, a search for all five categories of stormwater general permits was
performed. The search results are summarized in Table 15.

No MS4 permits are held in the watersheds of the Mission and Aransas Rivers. For
the Multi-sector and Concrete Production general permits, only the acreages
associated with active permits were tallied. These acreages were calculated by
importing the location information associated with the authorizations into a
Geographic Information System, and measuring the estimated disturbed area
based on the most recently available aerial imagery. For the Construction Activities
general permits, the authorization contains an “Area Disturbed” field. Due to the
variable and temporary nature of construction projects, it was preferable to average the acreages (on a monthly basis) associated with active permits over the entire available period of record (approximately 5 years). The results of this temporal averaging were used as representative of the average area under Construction Activities stormwater permits.

In order to calculate $W_L$, the Future Growth (FG) term must be known. The calculation for the FG term is presented in a later report section, but the results will be included here for continuity. Table 16 provides the information needed to compute $W_L$.

Implementation of WLAs

The TMDLs in this document will result in protection of existing beneficial uses and conform to Texas’s antidegradation policy. The three-tiered antidegradation policy in the State of Texas Surface Water Quality Standards prohibits an increase in loading that would cause or contribute to degradation of an existing use. The antidegradation policy applies to point source pollutant discharges. In general, antidegradation procedures establish a process for reviewing individual proposed actions to determine if the activity will degrade water quality.

The TCEQ intends to implement the individual WLAs through the permitting process as monitoring requirements and/or effluent limitations as required by the amendment of 30 Texas Administrative Code (TAC) Chapter 319 which became effective November 26, 2009. WWTFs discharging to the TMDL segments will be assigned an effluent limit based on the TMDL. Monitoring requirements are based on permitted flow rates and are listed in 30 TAC Section 319.9.

The permit requirements will be implemented during the routine permit renewal process. However, there may be a more economical or technically feasible means of achieving the goal of improved water quality and circumstances may warrant changes in individual WLAs after this TMDL is adopted. Therefore, the individual WLAs, as well as the WLAs for stormwater, are non-binding until implemented via a separate TPDES permitting action, which may involve preparation of an update to the state’s WQMP. Regardless, all permitting actions will demonstrate compliance with the TMDL.

The executive director or commission may establish interim effluent limits and/or monitoring-only requirements through a permit amendment or permit renewal. These interim limits will allow a permittee time to modify effluent quality in order to attain the final effluent limits necessary to meet the TCEQ and EPA approved TMDL allocations. The duration of any interim effluent limits may not be any longer than three years from the date of permit re-issuance. New permits will not contain interim effluent limits because compliance schedules are not allowed for a new permit.

Where a TMDL has been approved, domestic WWTF TPDES permits will require conditions consistent with the requirements and assumptions of the WLAs. For NPDES/TPDES-regulated municipal, construction stormwater discharges, and industrial stormwater discharges, water quality-based effluent limits (WQBELs) that implement the WLA for stormwater may be expressed as “system-wide requirements”, rather than as numeric effluent limits pertaining to specific discharge locations (EPA 2014).

Using an iterative adaptive approach to the maximum extent practicable is appropriate to address the stormwater component of this TMDL. Therefore, an
iterative, adaptive management approach will be used to address stormwater discharges. This approach encourages the implementation of structural or non-structural controls, implementation of mechanisms to evaluate the performance of the controls, and finally, allowance to make adjustments (e.g., more stringent controls or specific best management practices) as necessary to protect water quality.

**Updates to WLAs**

This TMDL is, by definition, the total of the sum of the WLA, the sum of the LA, and the MOS. Changes to individual WLAs may be necessary in the future in order to accommodate growth or other changing conditions. These changes to individual WLAs do not ordinarily require a revision of the TMDL document; instead, changes will be made through updates to the TCEQ’s WQMP. Any future changes to effluent limitations will be addressed through the permitting process and by updating the WQMP.

**Allowance for Future Growth**

The FG component of the TMDL equation addresses the requirement to account for future loadings that may occur due to population growth, changes in community infrastructure, and development. Specifically, this TMDL component takes into account the probability that new flows from WWTF discharges may occur in the future. The assimilative capacity of streams increases as the amount of flow increases. Increases in flow allow for additional indicator bacteria loads if the concentrations are at or below the contact recreation standard.

The allowance for FG will result in protection of existing beneficial uses and conform to Texas’s antidegradation policy.

Currently, 12 facilities that treat domestic wastewater are located within the watersheds of the Mission and Aransas Rivers; three in the Mission River watershed and nine in the Aransas River watershed (Table 18). To account for the FG component of the impaired segments, the loadings from all WWTFs are included in the FG computation, which is based on the WLA\textsubscript{WWTF} formula. The FG equation contains an additional term to account for projected population growth within the WWTF service areas between 2010 and 2050, based on data obtained from the TWDB 2017 State Water Plan Projections Data website (TWDB, 2013)

\[
\text{FG} = \text{Criterion} \times [\%\text{POP}_{2010-2050} \times \text{WWTFFP}] \times \text{Conversion Factor} \times (1 - F_{MOS})
\]

Where:

- Criterion = 35 MPN/100 mL (Enterococci)
%POP\textsubscript{2010-2050} = estimated percent increase in population between 2010 and 2050

WWTF\textsubscript{FP} = full permitted discharge (MGD)

Conversion Factor = 1.547 cfs/MGD \times 283.168 \, \text{mL/ft}^3 \times 86,400 \, \text{seconds/day}

F_{MOS} = fraction of loading assigned to margin of safety (5\% or 0.05)

The calculation results are shown in Table 18.

Compliance with these TMDLs is based on keeping the bacteria concentrations in the selected waters below the limits that were set as criteria for the individual sites. Future growth of existing or new point sources is not limited by these TMDLs as long as the sources do not cause bacteria to exceed the limits. The assimilative capacity of streams increases as the amount of flow increases. Consequently, increases in flow allow for increased loadings. The LDCs and tables in this TMDL will guide determination of the assimilative capacity of the stream under changing conditions, including future growth.

**Load Allocation**

The LA is the load from unregulated sources, and is calculated as:

\[ \text{LA} = \text{TMDL} - \text{WLA} - \text{FG} - \text{MOS} \]

Where:

\[ \text{LA} = \text{allowable loads from unregulated sources within the AU} \]

\[ \text{TMDL} = \text{total maximum daily load} \]

\[ \text{WLA} = \text{sum of all WWTF loads and all regulated stormwater loads} \]

\[ \text{FG} = \text{sum of future growth loads from potential permitted facilities} \]

\[ \text{MOS} = \text{margin of safety load} \]

The calculation results are shown in Table 19.

Summary of TMDL Calculations

Table 20 summarizes the TMDL calculations for the Mission River Tidal and Aransas River Tidal. Each of the TMDLs was calculated based on the median flow in the 0-10 percentile range (5% exceedance, high flow regime) for flow exceedance from the LDC developed for the downstream SWQM station within each watershed. Allocations are based on the current geometric mean criterion for Enterococci of 35 MPN/100 mL for each component of the TMDL.

* TMDL = Median flow (highest flow regime) * 35 MPN/100 mL * Conversion Factor; where the Conversion Factor = 283.168 100 mL/ft³ * 86,400 sec/day; Median Flow from Table 12

b MOS = 0.05 * TMDL

c WLA WWTFC = 35 MPN/day * Flows (MGD) * Conversion Factor * (1 – FMOS); where Flow is the full permitted flow from regulated discharging facilities (Table 14); Conversion Factor = 1.54723 cfs/MGD * 283.168 100 mL/ft³; FMOS = 5% or 0.05

d WLA SW = (TMDL - ΣWLA WWTFC - ΣFG - MOS) * FDA SW; (see Table 16)

e LA = TMDL - ΣWLA WWTFC - ΣWLA SW - ΣFG - MOS; (see Table 19)

f Future Growth = 35 MPN/100 mL * [%POP2010-2050 * WWTFFP] * Conversion Factor * (1 – FMOS); Conversion Factor = 1.54723 cfs/MGD * 283.168 100 mL/ft³; WWTFFP is full permitted flows and %POP2010-2050 is from Table 18

The final TMDL allocations (Table 21) needed to comply with the requirements of 40 CFR 130.7 include the future growth component within the WLA WWTFC.

In the event that the criterion changes due to future revisions in the state’s surface water quality standards, Appendix B provides guidance for recalculating the allocations in Table 21. Figures B-1 and B-2 of Appendix B were developed to
demonstrate how assimilative capacity, TMDL calculations, and pollutant load allocations change in relation to a number of proposed water quality criteria for Enterococci. The equations provided, along with Figures B-1 and B-2, allow calculation of new TMDLs and pollutant load allocations based on any potential new water quality criterion for Enterococci.

**Seasonal Variation**

Seasonal variations or seasonality occur(s) when there is a cyclic pattern in stream flow and, more importantly, in water quality constituents. Federal regulations (40 CFR 130.7(c)(1)) require that TMDLs account for seasonal variation in watershed conditions and pollutant loading.

Analysis of the seasonal differences in indicator bacteria concentrations were assessed by comparing Enterococci concentrations obtained from routine monitoring collected in the warmer months (May – September) against those collected during the cooler months (November – March). The months of April and October were considered transitional between the warm and cool seasons and were excluded from the seasonal analysis. Differences in Enterococci concentrations obtained in warmer versus cooler months were then evaluated by performing a Wilcoxon Rank Sum test on the original dataset. The nonparametric Wilcoxon Rank Sum test was selected because even with logarithmic transformation, the bacteria data were non-normally distributed. This analysis of Enterococci data indicated that there was a significant difference (α=0.05, p=0.0090) in indicator bacteria between cool and warm weather seasons only for the upstream station of the Aransas River Tidal (Station 12948, Segment 2003), where cool season concentrations were determined to be less than the warm season concentrations. Seasonality was not detected at the Aransas River Tidal downstream station (12947, Segment 2003), nor at the Mission River Tidal station (12943, Segment 2001).

**Public Participation**

The TCEQ maintains an inclusive public participation process. From the inception of the investigation, the project team sought to ensure that stakeholders were
informed and involved. Communication and comments from the stakeholders in the watershed strengthen TMDL projects and their implementation.

The TCEQ and Texas Water Resources Institute (TWRI) are jointly providing coordination for public participation in this project for development of the TMDL and the TMDL Implementation Plan (I-Plan). A series of public meetings were held over recent years to keep the public aware of the TMDL and to engage public participation in development of the I-Plan.

Public meetings were held in Refugio on January 30, 2012, March 28, 2012, May 30, 2012, August 1, 2012, November 29, 2012, February 19, 2013, April 11, 2013, May 21, 2013, July 11, 2013, and August 20, 2013. At many of the meetings, the main focus was development of the I-Plan, but at certain strategic meetings the participants were introduced to the TMDL process and progress on development of the TMDL. Notices of meetings were posted on the project Web page at both TWRI and TCEQ and on the TCEQ’s TMDL program’s online calendar. At least two weeks prior to scheduled meetings, the TWRI issued direct mailings and media releases and formally invited stakeholders to attend. To ensure that absent or new stakeholders could get information about past meetings and pertinent material, the TWRI project Web page provides meeting summaries, presentations, ground rules, and documents produced for review at <http://copanobay-wq.tamu.edu/meetings/>.

Implementation and Reasonable Assurance

The issuance of TPDES permits consistent with TMDLs provides reasonable assurance that WLAs in this TMDL report will be achieved. Per federal requirements, each TMDL is included in an update to the Texas WQMP as a plan element.

The WQMP coordinates and directs the state’s efforts to manage water quality and maintain or restore designated uses throughout Texas. The WQMP is continually updated with new, more specifically focused plan elements, as identified in federal regulations (CFR Section 130.6(c)). Commission adoption of a TMDL is the state’s certification of the associated WQMP update.

Because the TMDL does not reflect or direct specific implementation by any single pollutant discharger, the TCEQ certifies additional elements to the WQMP after the I-Plan is approved by the commission. Based on the TMDL and I-Plan, the TCEQ will propose and certify WQMP updates to establish required water-quality-based effluent limitations necessary for specific TPDES wastewater discharge permits.

No MS4 permits are held in the watersheds of the Mission and Aransas Rivers as of March 2013. However, population growth in these watersheds may require
Two TMDLs for Bacteria in the Mission and Aransas Rivers, Segments 2001 and 2003

urbanized areas within them to obtain Phase II MS4 stormwater permits in the future. For MS4 permits, the TCEQ will normally establish best management practices, which are a substitute for effluent limitations, as allowed by federal rules, where numeric effluent limitations are infeasible. When such practices are established in an MS4 permit, the TCEQ will not identify specific implementation requirements applicable to a specific TPDES storm water permit through an effluent limitation update. Rather, the TCEQ might revise a stormwater permit, require a revised Stormwater Management Program or Pollution Prevention Plan, or implement other specific revisions affecting stormwater dischargers in accordance with an adopted I-Plan.

Strategies for achieving pollutant loads in TMDLs from both point and nonpoint sources are reasonably assured by the state’s use of an I-Plan. The TCEQ is committed to supporting implementation of all TMDLs adopted by the commission.

I-Plans for Texas TMDLs use an adaptive management approach that allows for refinement or addition of methods to achieve environmental goals. This adaptive approach reasonably assures that the necessary regulatory and voluntary activities to achieve pollutant reductions will be implemented. Periodic, repeated evaluations of the effectiveness of implementation methods ascertain whether progress is occurring, and may show that the original distribution of loading among sources should be modified to increase efficiency. I-Plans will be adapted as necessary to reflect needs identified in evaluations of progress.

**Key Elements of an I-Plan**

An I-Plan includes a detailed description and schedule of the regulatory and voluntary management measures to implement the WLAs and LAs of particular TMDLs within a reasonable time. I-Plans also identify the organizations responsible for carrying out management measures, and a plan for periodic evaluation of progress.

Strategies to optimize compliance and oversight are identified in an I-Plan when necessary. Such strategies may include additional monitoring and reporting of effluent discharge quality to evaluate and verify loading trends, adjustment of an inspection frequency or a response protocol to public complaints, and escalation of an enforcement remedy to require corrective action of a regulated entity contributing to an impairment.

The TCEQ works with stakeholders and interested governmental agencies to develop and support I-Plans and track their progress. Work on the I-Plan begins during development of TMDLs. Because these TMDLs include potential agricultural sources of pollution, the TCEQ will also work in close partnership with the Texas State Soil and Water Conservation Board (TSSWCB) when developing.
the I-Plan. The TSSWCB is the lead agency in Texas responsible for planning, implementing, and managing programs and practices for preventing and abating agricultural and silvicultural nonpoint sources of water pollution. The cooperation required to develop an I-Plan will become a cornerstone for the shared responsibility necessary to carry it out.

Ultimately, the I-Plan will identify the commitments and requirements to be implemented through specific permit actions and other means. For these reasons, the I-Plan that is approved may not approximate the predicted loadings identified category-by-category in the TMDL and its underlying assessment. The I-Plan is adaptive for this very reason; it allows for continuous update and improvement.

In most cases, it is not practical or feasible to approach all TMDL implementation as a one-time, short-term restoration effort. This is particularly true when a challenging wasteload reduction or load reduction is required by the TMDL, there is high uncertainty with the TMDL analysis, there is a need to reconsider or revise the established water quality standard, or the pollutant load reduction would require costly infrastructure and capital improvements.

Appendix A.
Modified Load Duration Curve
Traditionally, the LDC approach has been restricted in TMDL development to freshwater, non-tidally influenced streams and rivers. The reason for excluding application of LDCs in TMDL development for tidally influenced stream and river systems is the presence of seawater in these river systems, i.e., an additional flow that has a loading. An assumption behind the LDC approach is that the loadings of bacteria are derived exclusively from the sources of the stream flows. These sources and their associated loadings may be varied, but it is inherently assumed that they may be computationally determined based on the stream flow at the selected exceedance frequency on the LDC used for the load allocation. But in a tidal system there is other water (i.e., seawater) that is a source with an associated loading that must be considered.

If the LDC approach is to be adapted to tidally influenced streams and rivers, some means of addressing the additional water and loadings from the seawater that mixes with freshwater in tidal rivers is needed. Oregon’s Umpqua Basin Bacteria TMDL provides a modification of the LDC approach that accounts for the seawater component (ODEQ, 2006).

Their approach is based on determining the volume of seawater that must be mixed with the volume of freshwater going down the river to arrive at the “observed” salinity using a simple mass balance approach as provided in the following:

\[(V_r + V_s) \times S_t = V_r \times S_r + V_s \times S_s\]  \hspace{1cm} (A-1)

Where

\[V_r = \text{volume daily river flow (m}^3) = Q \text{ (cfs)} \times 86,400 \text{ (sec/day)}; \text{where } Q = \text{river flow (cfs)}\]

\[V_s = \text{volume of seawater}\]

\[S_t = \text{salinity in river (parts per thousand or ppt)}\]

\[S_r = \text{background salinity of river water (ppt)}; \text{assumed to be close to 0 ppt}\]

\[S_s = \text{salinity of seawater (35 ppt)}\]

As noted in the computation of \(V_r\), the volumes are actually time-associated using a day as the temporal measure, thus providing the proper association for the daily pollutant load computation. Through algebraic manipulation this mass balance equation can be solved for the daily volume of seawater required to be mixed with freshwater (again, freshwater having an assumed salinity = 0) giving the equation found in the ODEQ (2006) technical information:

\[V_s = V_r / (S_s/S_t - 1)\]

for \(S_t >\) than background salinity; otherwise \(V_s = 0\)  \hspace{1cm} (A-2)
For the Umpqua Basin tidal streams (e.g., Figure A-1), as well as the present application to the Mission River Tidal and the Aransas River Tidal (Figures 6 and 7 in this report), regressions were developed of \( S_t \) to \( Q \) using measured salinity data \( (S_t) \) with freshwater flows \( (Q) \). These regressions all had some stream flow above which \( S_t = 0 \). The daily \( Q \) and regression-developed \( S_t \) were then used to compute \( V_s \). As \( S_t \) approaches zero, \( V_s \) likewise approaches a value of zero in Equation A-2, meaning the only flow present is the river flow \( (Q \text{ or } V_r) \).

**Figure A-1. Example salinity to flow regression from Umpqua Basin Tidal streams (ODEQ, 2006)**

It is also relevant to discuss the response of measured salinities at assessment stations to stream flow and the stream flows above which salinities approach background levels (again, assumed to be 0.0) within the context of FDCs for the Mission and Aransas Rivers. These FDCs and the plotted flow exceedance values where salinities approach background should be viewed from the perspective of TCEQ’s approach for bacteria TMDLs. Within the TCEQ TMDL approach with indicator bacteria, the highest flow regime is selected for developing the pollutant load allocation. This flow regime is defined as the range of 0-10% for the Mission
River Tidal and Aransas River Tidal. All the flows in the highest flow regime are greater than the amount of stream flow indicated by the regression analysis as needed to result in an absence of seawater.

The significance of the above observation is related to what happens within the modified LDC approach when salinities are at background. As salinity approaches background, $V_s$ in Equation A-2 approaches a value of zero, and in fact would be defined as zero when salinities are at background levels, resulting in the modified LDC flow volume ($V_s + V_r$) defaulting to the flow of the river, i.e., *no modification occurring to that portion of the LDC*. Therefore, regarding the pollutant load allocation process for the Mission River Tidal and Aransas River Tidal, the modified LDC method provides identical allowable loadings in the highest flow regime to those that would be computed using the standard LDC method that does not include tidal influences. The identical results of the modified and standard LDC method for the highest flow regime is the physical reality indicated in the observed salinity data. The data indicate that, at these elevated stream flows, seawater is effectively pushed completely out into Copano Bay. But the other implication, in hindsight, is that for these two tidal rivers, the same pollutant load allocation results would be determined with the LDC method with or without tidal influences being considered due to development of the TMDL for the higher stream flows.

Continuing with the theoretical development of the modified LDC for the Umpqua TMDLs, a total daily volume ($V_t$) is comprised of $V_r$ computed from $Q$ and the volume of seawater ($V_s$):

$$V_t = V_r + V_s$$  \hspace{1cm} (A-3)

Resulting in

$$\text{TMDL (MPN/day)} = \text{Criterion} \times V_t \times \text{Conversion factor}$$  \hspace{1cm} (A-4)

The actual FDCs developed for this TMDL using the modified LDC contain both a freshwater riverine flow component and a seawater component. For the Mission River Tidal, one FDC was created for Station 12943 (Figure A-2); for the Aransas River Tidal, the FDC used for the pollutant load allocation was created for Station 12947 (Figure A-3). For both Station 12943 on Mission River Tidal and Station 12947 on Aransas River Tidal, the amount of estimated seawater is provided on the FDC graphs. As expected from the equations, the amount of seawater present increases as both the freshwater flow decreases and the percent of days the flow is exceeded increases. Note that the x-axis direction of increase on the seawater plot is reversed from that on the FDC.

Appendix B.
Equations for Calculating TMDL Allocations for Changed Contact Recreation Standard
Equations for calculating new TMDL and allocations (in billion MPN/day)

\[ \text{TMDL} = 10.5869 \times \text{Std} \]
\[ \text{MOS} = 0.5293 \times \text{Std} \]
\[ \text{LA} = 10.0515 \times \text{Std} - 1.2902 \]
\[ \text{WLAWWTF} = 1.2910 \]
\[ \text{WLAsw} = 0.0061 \times \text{Std} - 0.0008 \]

Where:

- **Std** = Revised Contact Recreation Standard
- **MOS** = Margin of Safety
- **LA** = total load allocation (non-permitted source contributions)
- **WLAWWTF** = waste load allocation (permitted WWTF load + future growth)
  
  - [Note: WWTF load held at Primary Contact (35 MPN/100 mL) criteria]
- **WLAsw** = Waste load allocation (permitted stormwater)
Equations for calculating new TMDL and allocations (in billion MPN/day)

\[
TMDL = 4.2949 \times \text{Std}
\]

\[
MOS = 0.2147 \times \text{Std}
\]

\[
LA = 4.0786 \times \text{Std} - 10.5536
\]

\[
WLA_{\text{WWTF}} = 10.5575
\]

\[
WLA_{\text{sw}} = 0.0015 \times \text{Std} - 0.0040
\]

Where:

- \(Std\) = Revised Contact Recreation Standard
- \(MOS\) = Margin of Safety
- \(LA\) = total load allocation (non-permitted source contributions)
- \(WLA_{\text{WWTF}}\) = waste load allocation (permitted WWTF load + future growth)

[Note: WWTF load held at Primary Contact (35 MPN/100 mL) criteria]

\(WLA_{\text{sw}}\) = Waste load allocation (permitted stormwater)
